# Nonlinear elliptic systems with general growth 

Paolo Marcellini and Gloria Papi<br>Dipartimento di Matematica "U.Dini"<br>Università di Firenze - Viale Morgagni 67/A<br>I-50134 Firenze, Italy

#### Abstract

We prove local Lipschitz-continuity and, as a consequence, $C^{k}$ and $C^{\infty}$ regularity of weak solutions $u$ for a class of nonlinear elliptic differential systems of the form $\sum_{i=1}^{n} \frac{\partial}{\partial x_{i}} \alpha_{i}^{\alpha}(D u)=0, \alpha=1,2 \ldots m$. The growth conditions on the dependence of functions $a_{i}^{\alpha}(\cdot)$ on the gradient $D u$ are so mild to allow us to embrace growths between the linear and the exponential cases, and they are more general than those known in the literature.

Key words: Elliptic differential systems, calculus of variations, regularity.
AMS Subject Classification: 35J50, 35D10.

## 1 Introduction

Let $n \geq 2, m \geq 1$, let $\Omega$ be an open set of $\mathbb{R}^{n}$ and let $u: \Omega \subset \mathbb{R}^{n} \rightarrow \mathbb{R}^{m}$ be a weak solution of a nonlinear elliptic system of PDE's of the form

$$
\begin{equation*}
\sum_{i=1}^{n} \frac{\partial}{\partial x_{i}} a_{i}^{\alpha}(D u)=0, \quad \alpha=1,2 \ldots m \tag{1.1}
\end{equation*}
$$

where $D u: \Omega \subset \mathbb{R}^{n} \rightarrow \mathbb{R}^{m \times n}$ denotes the gradient of the map $u$, by components $x=\left(x_{i}\right)_{i=1,2, \ldots, n}, u=\left(u^{\alpha}\right)^{\alpha=1,2, \ldots, m}$ and $D u=\left(\partial u^{\alpha} / \partial x_{i}\right)=\left(u_{x_{i}}^{\alpha}\right)_{i=1,2, \ldots, n}^{\alpha=1,2, \ldots, m}$. By using the notation $\xi=\left(\xi_{i}^{\alpha}\right)_{i=1,2, \ldots, n}^{\alpha=1, \ldots, m}$, then $A(\xi)=\left(a_{i}^{\alpha}(\xi)\right)_{i=1,2, \ldots, n}^{\alpha=1, \ldots, m}$ is a given vector field $A: \mathbb{R}^{m \times n} \rightarrow \mathbb{R}^{m \times n}$ of class $C^{1}$, satisfying the ellipticity condition

$$
\begin{equation*}
\sum_{i, j=1}^{n} \sum_{\alpha, \beta=1}^{m} \frac{\partial a_{i}^{\alpha}(\xi)}{\partial \xi_{j}^{\beta}} \lambda_{i}^{\alpha} \lambda_{j}^{\beta}>0, \quad \forall \lambda, \xi \in \mathbb{R}^{m \times n}: \lambda \neq 0 \tag{1.2}
\end{equation*}
$$

as well as the variational condition that the vector field $A(\xi)$ is the gradient of a function $f(\xi)$; i.e., that there exists a function $f: \mathbb{R}^{m \times n} \rightarrow \mathbb{R}$ such that

$$
\begin{equation*}
a_{i}^{\alpha}=\frac{\partial f}{\partial \xi_{i}^{\alpha}}=f_{\xi_{i}^{\alpha}}, \quad \forall \alpha=1,2, \ldots, m ; \quad i=1,2, \ldots, n . \tag{1.3}
\end{equation*}
$$

Under the variational condition (1.3), the ellipticity condition (1.2) implies the (strict) convexity of the function $f$. Finally, we assume that $f(\xi)=g(|\xi|)$ is a function $g$ of the modulus $|\xi|$ (with $g^{\prime}(0)=0$, to respect the condition that the function $f$ is of class $\left.C^{1}\left(\mathbb{R}^{m \times n}\right)\right)$.
The regularity problem for the elliptic system (1.1) consists in asking if the solution $u=u(x)=\left(u^{\alpha}(x)\right)^{\alpha=1,2, \ldots, m}$, a-priori only a measurable function in the Sobolev class $W^{1,1}$, in fact is of class $C^{\infty}$ (or $C^{0, \alpha}, C^{1}, C^{1, \alpha}$, or $C^{k}$ for some $k$ ), under the assumption that the data are smooth.
With the aim to explain the situation, let us assume, for the moment, that the solution $u \in W^{1,1}$ in fact is also in $W_{\text {loc }}^{1, \infty}$; i.e., that the gradient $D u$ is locally bounded in $\Omega$. Then, under the ellipticity condition (1.2) and the variational condition (1.3) with $f(\xi)=g(|\xi|)$, it is possible to show that

$$
u \in W_{\mathrm{loc}}^{1, \infty}, \quad A \in C^{1} \quad \Longrightarrow \quad u \in C_{\mathrm{loc}}^{1, \alpha}
$$

(see for instance [23]; for simplicity of notations, we write $A \in C^{1}$ instead of, more precisely, $A \in C^{1, \gamma}$ for some $\left.\gamma \in(0,1)\right)$. Moreover, it is possible to see (cfr. [3], [18], [19], [20]) that $u$ admits second derivatives in weak form and that, for every $k \in\{1,2, \ldots, n\}$, the partial derivative $u_{x_{k}}=\left(u_{x_{k}}^{\beta}\right)^{\beta=1,2, \ldots, m}$ satisfies the elliptic differential linear system

$$
\sum_{i, j, \beta} \frac{\partial a_{i}^{\alpha}(D u(x))}{\partial \xi_{j}^{\beta}}\left(u_{x_{k}}\right)_{x_{j}}^{\beta}=0, \quad \alpha=1,2 \ldots m
$$

(see (4.4) and note that $\partial a_{i}^{\alpha} / \partial \xi_{j}^{\beta}=f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}}$. The coefficients $\partial a_{i}^{\alpha} / \partial \xi_{j}^{\beta}(D u(x))$ are locally Hölder-continuous, since $u \in C_{\text {loc }}^{1, \alpha}$; thus we can apply the regularity results in the literature for linear elliptic systems with smooth coefficients (see for instance Section 3 of Chapter 3 of [9]) to infer

$$
u \in C_{\mathrm{loc}}^{1, \alpha}, \quad A \in C^{k} \quad \Longrightarrow \quad u \in C_{\mathrm{loc}}^{k, \alpha}, \quad \forall k=2,3, \ldots
$$

In particular, $u \in C_{\text {loc }}^{\infty}$ if $A \in C^{\infty}$.
Therefore the problem which remains to be solved is: under which conditions on $A(\xi)$ is it possible to show that the gradient $D u$ is in fact locally bounded, i.e., $u \in W_{\mathrm{loc}}^{1, \infty}$.
Why the local boundedness of the gradient $D u$ is a so relevant condition for regularity?
Because the differential system (1.1) heavily depends on $D u$ in a nonlinear way, in particular trough $a_{i}^{\alpha}(D u)$ and, if $D u(x)$ is bounded, then $a_{i}^{\alpha}(D u(x))$ is bounded too
and far away from zero. Thus the behavior of $A(\xi)=\left(a_{i}^{\alpha}(\xi)\right)$ for $|\xi| \rightarrow+\infty$ becomes irrelevant.
On the contrary, the local boundedness of the gradient is a property related to the behavior of $A(\xi)$ as $|\xi| \rightarrow+\infty$. This problem has been extensively studied in the literature and a detailed story is presented in the next section. Precisely, in the next section we point out in details the assumptions made in the earlier mathematical literature on the subject, as well as the results presented in this paper.

We emphasize that the mathematical literature on the subject is large: some references are given in the next section and a good survey, as well as some new interesting regularity results, are given is the recent book by Bildhauer [2]. Our assumptions, in the context of basic elliptic systems of the type (1.1) with $A(\xi)=D_{\xi} f(\xi)$ and $f(\xi)=g(|\xi|)$, are more general then that ones in the literature, and they allow us to consider at the same time variational problems with functions $f(\xi)$ having linear growth as $|\xi| \rightarrow+\infty$, as well as functions $f(\xi)$ with either polynomial or exponential growth at infinity.

## 2 Description of the problem and statement of the main results

Let $\Omega$ be an open set of $\mathbb{R}^{n}$ for some $n \geq 2$ and let $u: \Omega \rightarrow \mathbb{R}^{m}(m \geq 1)$ be a vector valued local minimizer of an integral of the calculus of variations of the type

$$
\begin{equation*}
\mathcal{F}=\int_{\Omega} f(D u) d x \tag{2.1}
\end{equation*}
$$

related to some convex integrand $f: \mathbb{R}^{m \times n} \rightarrow \mathbb{R}$. Here $D u: \Omega \subset \mathbb{R}^{n} \rightarrow \mathbb{R}^{m \times n}$ denotes the gradient of the map $u$. By a local minimizer of the integral (2.1) we mean a function $u \in W_{\text {loc }}^{1,1}\left(\Omega ; \mathbb{R}^{m}\right)$ with the property that $\mathcal{F}(u) \leq \mathcal{F}(u+\phi)$ for every $\phi \in C_{0}^{1}\left(\Omega ; \mathrm{R}^{m}\right)$; in the context of this paper this definition is consistent. It is well known that in general we cannot expect that $u$, a-priori either minimizer of the integral (2.1) or weak solution of the differential system (1.1) in a Sobolev class of functions $W^{1, p}\left(\Omega ; \mathbb{R}^{m}\right)$, is in fact a smooth function, say of class $C_{l o c}^{\infty}$, or even of class $C_{l o c}^{1}$ or $C_{l o c}^{0, \alpha}$ for some $\alpha \in(0,1)$. In the vector-valued case $m>2$ examples of non smooth minimizers and of non smooth weak solutions have been given by De Giorgi [6], Giusti-Miranda [12] and by Necas [15]. A recent counterexample in three dimensional case in the context of smooth strongly convex functionals has been also given by Sverak-Yan [22].

Even in the scalar case $m=1$ it is possible to give examples of local minimizers $u \in W_{l o c}^{1, p}(\Omega ; \mathbb{R})$ for some $p>1$ (this phenomenon is related to the $p, q$-growth condition described below, with $q$ larger than $p$ ), which do nor even belong to $L_{\text {loc }}^{\infty}(\Omega ; \mathbb{R})$; see [10], [17], [18], [19].

As already mentioned, regularity of solutions is often related to the growth of $f(\xi)$ as $|\xi| \rightarrow+\infty$. More precisely, the so-called natural growth conditions state that there exists a growth exponent $p>1$ and positive constants $m, M$ such that

$$
\begin{equation*}
m|\xi|^{p} \leq f(\xi) \leq M\left(1+|\xi|^{p}\right), \quad \forall \xi \in \mathbb{R}^{m \times n} \tag{2.2}
\end{equation*}
$$

as well as the ellipticity conditions on the matrix $D^{2} f$ of the second derivatives of $f$, of the type

$$
\begin{equation*}
m\left(1+|\xi|^{p-2}\right)|\lambda|^{2} \leq\left(D^{2} f(\xi) \lambda, \lambda\right) \leq M\left(1+|\xi|^{p-2}\right)|\lambda|^{2}, \quad \forall \xi, \lambda \in \mathbb{R}^{m \times n} \tag{2.3}
\end{equation*}
$$

It was pointed out by Marcellini in [18], [19] that the above natural growth conditions, sufficient for regularity, can be weakened into anisotropic growth conditions, or into $p, q-$ growth conditions; i.e., with an exponent $q \geq p$ in the right hand side of (2.2), (2.3), or into more general growth conditions. In particular, ellipticity $p, q$-growth conditions of the type

$$
\begin{equation*}
m\left(1+|\xi|^{p-2}\right)|\lambda|^{2} \leq\left(D^{2} f(\xi) \lambda, \lambda\right) \leq M\left(1+|\xi|^{q-2}\right)|\lambda|^{2}, \quad \forall \xi, \lambda \in \mathbb{R}^{m \times n} \tag{2.4}
\end{equation*}
$$

with exponents $q \geq p>1$ such that $\frac{q}{p}<\frac{n}{n-2}$ if $n>2$.
In the general vectorial setting only a few contributions are available for general growth: we like to refer to the papers by Giusti [11], Giusti-Miranda [13], Acerbi-Fusco [1] and by Esposito-Leonetti-Mingione [7]. A recent book by Bildhauer [2] gives a complete overview and a detailed list of references. If some additional structure conditions are assumed then several results can be found in the mathematical literature on the subject. For instance, as a generalization of the " $p$ - growth" case considered by Uhlenbeck [23], Marcellini proposed in [21] an approach to the regularity of minimizers of the integral

$$
\begin{equation*}
F(u)=\int_{\Omega} g(|D u|) d x \tag{2.5}
\end{equation*}
$$

i.e. with the integrand in (2.1) of the form $f(\xi)=g(|\xi|)$, where $g:[0,+\infty) \rightarrow[0,+\infty)$ is an increasing convex function, without growth assumption on $g(t)$ as $t \rightarrow+\infty$. For example, the regularity result can be applied to the exponential growth, such as any finite composition of the type

$$
\begin{equation*}
f(\xi)=\left(\exp \left(\ldots\left(\exp \left(\exp |\xi|^{2}\right)^{p_{1}}\right)^{p_{2}}\right) \ldots\right)^{p_{k}} \tag{2.6}
\end{equation*}
$$

with $p_{i} \geq 1, \forall i=1,2 \ldots k$. However, some other restrictions ware imposed in [21], such as, for instance, the fact that $t \in(0,+\infty) \rightarrow \frac{g^{\prime}(t)}{t}$ is assumed to be an increasing function. To exemplify, the model case $g(t)=t^{p}$ gives the restriction $p \geq 2$. Afterwards, in [14] Leonetti-Mascolo-Siepe consider the case of subquadratic $p, q$-growth conditions, i.e. in (2.4) they assume $1<p<q<2$. Their result includes energy densities $f$ of the type $f(\xi)=|\xi|^{p} \log ^{\alpha}(1+|\xi|)$ with $p<2$. In [8] Fuchs-Mingione concentrate on the
case of nearly-linear growth, for which (2.4) fails to be true. Typical examples are the logarithmic case $f(\xi)=|\xi| \log (1+|\xi|)$ and its iterated version

$$
\begin{cases}f_{k}(\xi) & =|\xi| L_{k}(|\xi|)  \tag{2.7}\\ L_{s+1}(t) & =\log \left(1+L_{s}(t)\right), \quad L_{1}(t)=\log (1+t)\end{cases}
$$

for $k \in$ arbitrary. Bildhauer in [2] considers linear behaviors for the functional (2.5); he gives conditions that can keep $\gamma$-elliptic linear growth with $\gamma<1+\frac{2}{n}$. Examples of $\gamma$-elliptic linear integrands are given by

$$
\begin{equation*}
g_{\gamma}(t)=\int_{0}^{t} \int_{0}^{s}\left(1+z^{2}\right)^{-\frac{\gamma}{2}} d z d s, \quad \forall t \geq 0 \tag{2.8}
\end{equation*}
$$

For $\gamma=1, g_{\gamma}(t)$ behaves like $t \log (1+t)$ and in the limit case $\gamma=3, g_{\gamma}(t)$ becomes $(1+$ $\left.t^{2}\right)^{1 / 2}$. Hence the functions $g_{\gamma}(t)$ provide a one parameter family connecting logarithmic examples with the minimal surface integrand.
As further reference see also [4].
In this paper we are engaged to find conditions which include different kind of growths. At this purpose we give a general condition on function $g$ embracing growths moving between linear and exponential functions. The condition is the following:

Let $t_{0}, H>0$ and $\beta \in\left(\frac{1}{n}, \frac{2}{n}\right)$. For every $\alpha \in\left(1, \frac{n}{n-1}\right]$ there exists $K=K(\alpha)$ such that

$$
\begin{equation*}
H t^{-2 \beta}\left[\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{n-2}{n}}+\frac{g^{\prime}(t)}{t}\right] \leq g^{\prime \prime}(t) \leq K\left[\frac{g^{\prime}(t)}{t}+\left(\frac{g^{\prime}(t)}{t}\right)^{\alpha}\right], \quad \forall t \geq t_{0} \tag{2.9}
\end{equation*}
$$

The exponent $\alpha$ in the right hand side is a parameter to play; i.e., to use to test more functions $g$. The condition in the left-hand side of (2.9) permits to achieve functions, for instance, with second derivative going to zero as a power $t^{-\gamma}$, (i.e. $\gamma$-elliptic ), where $\gamma$ is not too large and is related to the dimension $n$, i.e. $\gamma<1+\frac{2}{n}$. As well as functions in (2.8), others examples in the linear case include:

$$
g(t)=1+t-\sqrt{t}, \quad \forall t \geq 1, \quad n<4
$$

or more in general, for $r \in(0,1)$,

$$
g_{r}(t)=h(t)-t^{r}, \quad \forall t \geq 1, \quad n<\frac{2}{1-r}
$$

and also

$$
g_{r}(t)=h(t)+\left(1-t^{r}\right)^{\frac{1}{r}}, \quad \forall t \geq 1, \quad n<\frac{2}{r}
$$

where $h(t)$ is a convex function such that, for suitable constants $C_{1}, C_{2}$,

$$
C_{1}(1+t) \leq h(t) \leq C_{2}(1+t)
$$

We observe that the functions $g_{k}(t)=\left(1+t^{k}\right)^{\frac{1}{k}}$, related to minimal surfaces, are convex if $k \geq 1$, and $g_{k}^{\prime \prime}(t)=(k-1) t^{k-2}\left(1+t^{k}\right)^{\frac{1}{k}-2}=\mathcal{O}\left(\frac{1}{t^{k+1}}\right)$ when $t \rightarrow+\infty$, so that they do not satisfy left-hand side of condition (2.9).
As far as $p, q$-growth is concerned, we like to remark that condition (2.9) is satisfied without assuming any restriction on $p$ and $q$. For example, fixed $1<p<q$, consider the function (cfr. [5])

$$
g(t)= \begin{cases}t^{p} & \text { if } t \leq \tau_{0}  \tag{2.10}\\ t^{\frac{p+q}{2}+\frac{q-p}{2} \sin \log \log \log t} & \text { if } t>\tau_{0}\end{cases}
$$

where $\tau_{0}$ is such that $\sin \log \log \log \tau_{0}=-1$. First of all we observe that function $g$ oscillates between the function $t^{p}$, to which it is tangent in $\tau_{n}$ such that $\sin \log \log \log \tau_{n}=$ -1 , and the function $t^{q}$, to which it is tangent in $\sigma_{n}$ such that $\sin \log \log \log \sigma_{n}=1$. By a direct computation it is possible to see that one can choose $\tau_{0}$ and $t_{0}$ large enough such that $g$ is convex and satisfies (2.9). We observe that the left-hand side of (2.9) implies $g^{\prime \prime}(t)>0$ for $t \geq t_{0}$. For this reason the function in (2.10), with $p=1$, does not satisfy condition (2.9); in fact if $p=1$ we have $g^{\prime \prime}\left(\sigma_{n}\right)=0$.

Also high growths like that in (2.6) are included in condition (2.9). In other words our results unify and generalize that ones obtained in the literature for the integral (2.5), including in particular the linear case treated in [2], the non-standard $p, q-$ growth, the exponential growth considered in [21] and also the new example of oscillating function in (2.10). Part of the techniques of this paper have been introduced by Marcellini in [21]. The starting point is the second variational weak equation for which we need the supplementary assumption that $g^{\prime \prime}(t)$ and $\frac{g^{\prime}(t)}{t}$ are bounded by constants $N$ and $M$ for all $t>0$. In this case we give $a$-priori estimates for $\sup |D(u)|$ by using only the properties of function $g$, so that the constants in the a-priori bounds do not depend on $M$ and $N$. Successively we remove this assumption by approximating the original problem with regular variational ones. This is possible because the constants $N$ and $M$ do not enter in the $a$-priori bounds for the $L^{\infty}$-norm of the gradient.

In this paper we prove in particular the following two results, the first one valid under general growth conditions, the second one specific for the linear case.

Theorem A (General growth) Let $g:[0,+\infty) \rightarrow[0,+\infty)$ be a convex function of class $W_{\text {loc }}^{2, \infty}$ with $g(0)=g^{\prime}(0)=0$, satisfying the general growth condition (2.9) with $\beta \in\left(\frac{1}{n}, \frac{2}{n}\right)$ as before. Let $u \in W_{\text {loc }}^{1,1}\left(\Omega ; R^{m}\right)$ be a local minimizer of the integral (2.5). Then $u \in W_{\mathrm{loc}}^{1, \infty}\left(\Omega ; R^{m}\right)$. Moreover the following estimate holds: for every $\epsilon>0$ and $R>\rho>0$ there exists a constant $C$ (depending on $\epsilon, n, \rho, R, H, K$ and $\sup _{0 \leq t \leq t_{0}} g^{\prime \prime}(t)$ )
such that

$$
\begin{equation*}
\|D u\|_{L^{\infty}\left(B \rho ; \mathbb{R}^{m \times n}\right)}^{2-\beta n} \leq C\left\{\int_{B_{R}}(1+g(|D u|)) d x\right\}^{\frac{1}{1-\beta}+\epsilon} \tag{2.11}
\end{equation*}
$$

Theorem B (Linear growth) Let $g:[0,+\infty) \rightarrow[0,+\infty)$ be a convex function of class $W_{\mathrm{loc}}^{2, \infty}$ with $g(0)=g^{\prime}(0)=0$. Let us assume that $g$ has the linear behavior at infinity

$$
\begin{equation*}
\lim _{t \rightarrow+\infty} \frac{g(t)}{t}=l \in(0,+\infty) \tag{2.12}
\end{equation*}
$$

and that its second derivative satisfies the inequalities

$$
\begin{equation*}
H \frac{1}{t^{\gamma}} \leq g^{\prime \prime}(t) \leq K \frac{1}{t}, \quad \forall t \geq t_{0} \tag{2.13}
\end{equation*}
$$

for some positive constants $H, K, t_{0}$ and for some $\gamma \in\left[1,1+\frac{2}{n}\right)$. Then every local minimizer $u$ of the integral (2.5) is of class $W_{\text {loc }}^{1, \infty}\left(\Omega ; R^{m}\right)$ and, for every $R>\rho>0$ the following estimate is satisfied

$$
\begin{equation*}
\|D u\|_{L^{\infty}\left(B \rho ; \mathbb{R}^{m \times n}\right)}^{2-\beta n} \leq C \int_{B_{R}}(1+g(|D u|)) d x \tag{2.14}
\end{equation*}
$$

where $\beta=\frac{\gamma}{2}-\frac{n-2}{2 n}$ and the constant $C$ depends on $n, \rho, R, l, H, K$ and $\sup _{0 \leq t \leq t_{0}} g^{\prime \prime}(t)$.
Note that $2-\beta n \in(0,1]$ since $\gamma \in\left[1,1+\frac{2}{n}\right)$. Note also that the estimate (2.14) in Theorem B is sharper than the estimate (2.11) of Theorem A, when we reduce the general assumption (2.9) of Theorem A to linear growth, since in the second case the proof is more direct, as explained at the end of this paper. Therefore Theorem B cannot be considered a particular case of Theorem A.
The plan of the paper is the following. In Section 2 we discuss some consequences of assumption (2.9) and we prove for $g$ some estimates that will be used in Section 3, where we get a-priori bounds for the gradient of local minimizers of functional (2.5). In Section 4 we define the approximating regular variational problems and we obtain a-priori bounds for the gradient of their minimizers. Finally in Section 5 we go to the limit and we obtain the regularity Theorems A and B.

## 3 Ellipticity estimates and their consequences

With the aim to study integrals of the Calculus of Variations of the type (2.5), we consider $f(\xi)=g(|\xi|)$, for $\xi \in \mathbb{R}^{m \times n},\left(\xi=\left(\xi_{i}^{\alpha}\right), i=1,2, \ldots, n, \alpha=1,2, \ldots m\right)$, where

$$
g:[0,+\infty) \rightarrow[0,+\infty) \quad \begin{array}{ll}
\text { is a convex function of class }  \tag{3.1}\\
W^{2, \infty}[0, T], \forall T>0, \quad g(0)=g^{\prime}(0)=0
\end{array}
$$

By the representation $f(\xi)=g(|\xi|)$, we have

$$
\begin{equation*}
f_{\xi_{i}^{\alpha}}=g^{\prime}(|\xi|) \frac{\xi_{i}^{\alpha}}{|\xi|}, \quad f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}}=\left(\frac{g^{\prime \prime}(|\xi|)}{|\xi|^{2}}-\frac{g^{\prime}(|\xi|)}{|\xi|^{3}}\right) \cdot \xi_{i}^{\alpha} \xi_{j}^{\beta}+\frac{g^{\prime}(|\xi|)}{|\xi|} \delta_{\xi_{i}^{\alpha} \xi_{j}^{\beta}} . \tag{3.2}
\end{equation*}
$$

Since

$$
\sum_{i, j, \alpha, \beta} \xi_{i}^{\alpha} \xi_{j}^{\beta} \lambda_{i}^{\alpha} \lambda_{j}^{\beta}=\left(\sum_{i, \alpha} \xi_{i}^{\alpha} \lambda_{i}^{\alpha}\right)^{2} \leq(|\xi||\lambda|)^{2}, \quad \forall \lambda, \xi \in \mathbb{R}^{m \times n}
$$

(and the equality holds when $\lambda$ is proportional to $\xi$ ), then we easily obtain the following ellipticity estimates

$$
\begin{equation*}
\min \left\{g^{\prime \prime}(|\xi|), \frac{g^{\prime}(|\xi|)}{|\xi|}\right\} \leq \frac{\sum_{i, j, \alpha, \beta} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}} \lambda_{i}^{\alpha} \lambda_{j}^{\beta}}{|\lambda|^{2}} \leq \max \left\{g^{\prime \prime}(|\xi|), \frac{g^{\prime}(|\xi|)}{|\xi|}\right\}, \quad \forall \lambda, \xi \in \mathbb{R}^{m \times n} \tag{3.3}
\end{equation*}
$$

Let us define

$$
\begin{equation*}
\mathcal{H}(t)=\max \left\{g^{\prime \prime}(t), \frac{g^{\prime}(t)}{t}, \forall t>0\right\} \tag{3.4}
\end{equation*}
$$

We observe that, since $g^{\prime}(t)=\int_{0}^{t} g^{\prime \prime}(s) d s \leq M_{T} t,, \forall t \leq T$ then the function $\frac{g^{\prime}(t)}{t}$ (and consequently $\mathcal{H}(t))$ is bounded on $(0, T], \forall T>0$. We observe that in (3.1) we do not assume $g^{\prime}(0)>0$ but, more generally, we allow $g^{\prime}(t)$ and $g(t)$ to be equal to zero in $(0, \bar{t}]$, with $\bar{t}>0$. The sequel of this section is devoted to derive some useful estimates on the function $g$, starting by the general assumption (2.9). With this aim we begin with the following lemma (were by $2^{*}$ we denote the Sobolev's exponent, i.e $2^{*}=\frac{2 n}{n-2}$ if $n \geq 3$, while $2^{*}$ is any fixed number greater than 2 if $n=2$ ).

Lemma 3.1 Let $g$ be as in (3.1). Let $\beta, H$ positive constants such that $\frac{1}{n}<\beta<\frac{2}{n}$. Let us assume that for every $\alpha \in\left(1, \frac{n}{n-1}\right]$ there exists a constant $K$ (depending on $\alpha$ ) such that

$$
\begin{equation*}
H t^{-2 \beta}\left[\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{2}{2^{*}}}+\frac{g^{\prime}(t)}{t}\right] \leq g^{\prime \prime}(t) \leq K\left[\frac{g^{\prime}(t)}{t}+\left(\frac{g^{\prime}(t)}{t}\right)^{\alpha}\right], \quad \forall t \geq t_{0} \tag{3.5}
\end{equation*}
$$

Then for every $\delta$ with $\frac{2 \alpha}{2-\alpha} \leq \delta \leq 2^{*}$ and for every $\gamma \geq 0$ there exists a constant $C$ such that

$$
\begin{equation*}
1+\int_{0}^{t} s^{\gamma} \sqrt{g^{\prime \prime}(s)} d s \geq C\left[1+\left(\frac{t^{\gamma+1-\beta}}{\gamma+1}\right)^{\delta} \mathcal{H}(t)\right]^{\frac{1}{\delta}}, \quad \forall t \geq 0 \tag{3.6}
\end{equation*}
$$

Proof. In order to simplify this proof, up to a rescaling, we will assume, without lost on generality, that $t_{0}=1$ and $g\left(t_{0}\right)>0$. We observe that

$$
\begin{equation*}
\left[1+\left(\frac{t^{\gamma+1-\beta}}{\gamma+1}\right)^{\delta} \mathcal{H}(t)\right]^{\frac{1}{\delta}} \leq\left[1+\left(\frac{t^{\gamma+1-\beta}}{\gamma+1}\right) \mathcal{H}(t)^{\frac{1}{\delta}}\right], \quad \forall t>0, \forall \gamma \geq 0 \tag{3.7}
\end{equation*}
$$

Now, let us call

$$
\begin{align*}
& F_{1}(t, \gamma)=1+\int_{0}^{t} s^{\gamma} \sqrt{g^{\prime \prime}(s)} d s  \tag{3.8}\\
& G_{1}(t, \gamma)=1+\left(\frac{t^{\gamma+1-\beta}}{\gamma+1}\right) \mathcal{H}(t)^{\frac{1}{\delta}} \tag{3.9}
\end{align*}
$$

and let us define the quotient

$$
\begin{equation*}
Q_{1}(t, \gamma)=\frac{F_{1}(t, \gamma)}{G_{1}(t, \gamma)} \tag{3.10}
\end{equation*}
$$

It is easy to see that $Q_{1}(t, \gamma)$ is lower bounded in the strip $(t, \gamma) \in\left[0, t_{0}\right] \times[0,+\infty]$ (we remember that $t_{0}=1$ ) by the constant $C_{1}=\left(1+\max _{0<t \leq 1}\left[\frac{g^{\prime}(t)}{t}+g^{\prime \prime}(t)\right]^{\frac{1}{\delta}}\right)^{-1}$. From this (3.6) follows for $0 \leq t \leq t_{0}$. Now let $t \geq t_{0}$. By the definition (3.4) of function $\mathcal{H}(t)$ we get

$$
\mathcal{H}(t) \leq \frac{g^{\prime}(t)}{t}+g^{\prime \prime}(t)
$$

and by the right-hand side of (3.5) we can write

$$
\begin{equation*}
\mathcal{H}(t) \leq(K+1)\left[\frac{g^{\prime}(t)}{t}+\left(\frac{g^{\prime}(t)}{t}\right)^{\alpha}\right] \tag{3.11}
\end{equation*}
$$

From this, instead to prove (3.6) we can prove the following

$$
\begin{equation*}
1+\int_{0}^{t} s^{\gamma} \sqrt{g^{\prime \prime}(s)} d s \geq C\left[1+\frac{t^{\gamma+1-\beta}}{\gamma+1}\left[\frac{g^{\prime}(t)}{t}+\left(\frac{g^{\prime}(t)}{t}\right)^{\alpha}\right]^{\frac{1}{\delta}}\right], \quad \forall t \geq t_{0} \tag{3.12}
\end{equation*}
$$

(where we still denote by $C$ the new constant). At this end it is sufficient to show the inequality between the derivatives side to side with respect to $t$ of (3.12)

$$
\begin{equation*}
\sqrt{g^{\prime \prime}(t)} \geq C_{1} t^{-\beta}\left[\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{1}{\delta}}+\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{\alpha}{\delta}}+\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{1}{\delta}-1} g^{\prime \prime}(t)+\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{\alpha}{\delta}-1} g^{\prime \prime}(t)\right] \tag{3.13}
\end{equation*}
$$

or, since $\alpha>1$,

$$
\left\{\begin{array}{l}
\sqrt{g^{\prime \prime}(t)} \geq 2 C_{1} t^{-\beta}\left[\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{1}{\delta}}+\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{1}{\delta}-1} g^{\prime \prime}(t)\right], \text { if } \frac{g^{\prime}(t)}{t} \leq 1 \\
\sqrt{g^{\prime \prime}(t)} \geq 2 C_{1} t^{-\beta}\left[\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{\alpha}{\delta}}+\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{\alpha}{\delta}-1} g^{\prime \prime}(t)\right], \text { if } \frac{g^{\prime}(t)}{t} \geq 1
\end{array}\right.
$$

If $\frac{g^{\prime}(t)}{t} \leq 1$ by the left-hand side of (3.5) we get, since $\frac{1}{\delta} \geq \frac{1}{2^{*}}$,

$$
\begin{equation*}
\sqrt{g^{\prime \prime}(t)} \geq \sqrt{H} t^{-\beta}\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{1}{2^{*}}} \geq \sqrt{H} t^{-\beta}\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{1}{\delta}} \tag{3.14}
\end{equation*}
$$

and also, by the right-hand side of (3.5)

$$
g^{\prime \prime}(t)\left(\frac{g^{\prime}(t)}{t}\right)^{-1} \leq 2 K
$$

As a result we have

$$
\begin{equation*}
\sqrt{g^{\prime \prime}(t)} \geq \frac{\sqrt{H}}{2 K} t^{-\beta}\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{1}{\delta}} 2 K \geq \frac{\sqrt{H}}{2 K} t^{-\beta}\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{1}{\delta}-1} g^{\prime \prime}(t) \tag{3.15}
\end{equation*}
$$

Adding (3.14) to (3.15) we get, if $\frac{g^{\prime}(t)}{t} \leq 1$,

$$
\begin{equation*}
\sqrt{g^{\prime \prime}(t)} \geq \frac{\sqrt{H}}{4 K} t^{-\beta}\left[\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{1}{\delta}}+\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{1}{\delta}-1} g^{\prime \prime}(t)\right] . \tag{3.16}
\end{equation*}
$$

If $\frac{g^{\prime}(t)}{t} \geq 1$, with similar arguments we have

$$
\begin{equation*}
\sqrt{g^{\prime \prime}(t)} \geq \sqrt{H} t^{-\beta}\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{1}{2}} \tag{3.17}
\end{equation*}
$$

and since $\delta \geq \frac{2 \alpha}{2-\alpha}>2 \alpha$, i.e. $\frac{\alpha}{\delta}<\frac{1}{2}$, we get

$$
\begin{equation*}
\sqrt{g^{\prime \prime}(t)} \geq \sqrt{H} t^{-\beta}\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{\alpha}{\delta}} \tag{3.18}
\end{equation*}
$$

Moreover, by the right-hand side of (3.5) we get

$$
\sqrt{g^{\prime \prime}(t)} \leq \sqrt{2 K}\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{\alpha}{2}}
$$

equivalently

$$
g^{\prime \prime}(t) \leq \sqrt{2 K}\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{\alpha}{2}} \sqrt{g^{\prime \prime}(t)}
$$

and, since $t \geq t_{0}=1$, we can also write

$$
\sqrt{g^{\prime \prime}(t)} \geq \frac{1}{\sqrt{2 K}}\left(\frac{g^{\prime}(t)}{t}\right)^{-\frac{\alpha}{2}} g^{\prime \prime}(t) \geq\left(\frac{1}{\sqrt{2 K}}\right) t^{-\beta}\left(\frac{g^{\prime}(t)}{t}\right)^{-\frac{\alpha}{2}} g^{\prime \prime}(t) .
$$

Since $\delta \geq \frac{2 \alpha}{2-\alpha}$, i.e. $\frac{\alpha}{\delta} \leq \frac{2-\alpha}{2}$, we have $\frac{\alpha}{\delta}-1 \leq-\frac{\alpha}{2}$; hence

$$
\begin{equation*}
\sqrt{g^{\prime \prime}(t)} \geq\left(\frac{1}{\sqrt{2 K}}\right) t^{-\beta}\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{\alpha}{\delta}-1} g^{\prime \prime}(t) \tag{3.19}
\end{equation*}
$$

Therefore, in the case $\frac{g^{\prime}(t)}{t} \geq 1$, from (3.18) and (3.19) we obtain

$$
\begin{equation*}
\sqrt{g^{\prime \prime}(t)} \geq \min \left\{\frac{\sqrt{H}}{2}, \frac{1}{2 \sqrt{2 K}}\right\} t^{-\beta}\left[\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{\alpha}{\delta}}+\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{\alpha}{\delta}-1} g^{\prime \prime}(t)\right] \tag{3.20}
\end{equation*}
$$

Therefore (3.13) holds for $t \geq t_{0}$ too, as consequence of (3.16) and (3.20).

Lemma 3.2 Let $g$ be as in (3.1). Suppose that $g$ satisfies the right-hand side of condition (3.5). Then there exists a constant $C$, depending on $K, g^{\prime}\left(t_{0}\right), t_{0}, \alpha$, such that

$$
\begin{equation*}
g^{\prime}(t) t \leq C(1+g(t))^{\frac{1}{2-\alpha}}, \quad \forall t \geq 0 . \tag{3.21}
\end{equation*}
$$

Proof. Let $t \geq t_{0}=1$. A multiplication for $t$ and an integration side to side in the right-hand side of (3.5) give

$$
\int_{t_{0}}^{t} s g^{\prime \prime}(s) d s \leq K \int_{t_{0}}^{t} g^{\prime}(s) d s+K \int_{t_{0}}^{t} s\left(\frac{g^{\prime}(s)}{s}\right)^{\alpha} d s
$$

An integration by parts of the left-hand side in the previous inequality get

$$
g^{\prime}(t) t \leq g^{\prime}\left(t_{0}\right) t_{0}+(K+1) \int_{t_{0}}^{t} g^{\prime}(s) d s+K \int_{t_{0}}^{t} s^{2-2 \alpha} g^{\prime}(s)\left(g^{\prime}(s) s\right)^{\alpha-1} d s
$$

Since $g\left(t_{0}\right) \geq 0$ and $t \geq t_{0}$ we have

$$
g^{\prime}(t) t \leq g^{\prime}\left(t_{0}\right) t_{0}+(K+1) g(t)+K t_{0}^{2-2 \alpha}\left(g^{\prime}(t) t\right)^{\alpha-1} g(t)
$$

By dividing both sides for $\left(g^{\prime}(t) t\right)^{\alpha-1}$ we obtain

$$
\left(g^{\prime}(t) t\right)^{2-\alpha} \leq\left(g^{\prime}\left(t_{0}\right) t_{0}\right)^{2-\alpha}+\left(\frac{K+1}{\left(g^{\prime}\left(t_{0}\right) t_{0}\right)^{\alpha-1}}+K t_{0}^{2-2 \alpha}\right) g(t)
$$

Let $C_{1}{ }^{2-\alpha}=\max \left\{\left(g^{\prime}\left(t_{0}\right) t_{0}\right)^{2-\alpha}, \frac{K+1}{\left(g^{\prime}\left(t_{0}\right) t_{0}\right)^{\alpha-1}}+K t_{0}{ }^{2-2 \alpha}\right\}$. Then we have for all $t \geq t_{0}$

$$
g^{\prime}(t) t \leq C_{1}(1+g(t))^{\frac{1}{2-\alpha}}
$$

Finally (3.21) follows with $C \geq C_{1}$ because $g^{\prime}(t) t \leq g^{\prime}\left(t_{0}\right) t_{0}$, for all $t \leq t_{0}$.

Lemma 3.3 Let $g$ be as in (3.1) and let $\mathcal{H}$ be the function defined in (3.4) . Suppose that $g$ satisfies the right-hand side of condition (3.5). Then there exists a constant $C$ such that for any $\eta, 1<\eta \leq \frac{3 n}{3 n-4}$,

$$
\begin{equation*}
1+\mathcal{H}(t) t^{2} \leq C(1+g(t))^{\eta}, \quad \forall t \geq 0 \tag{3.22}
\end{equation*}
$$

where $\eta=\eta(\alpha)=\frac{\alpha}{2-\alpha}$ and the constant $C$ depends on $K, \sup _{0 \leq t \leq t_{0}} g^{\prime \prime}(t), \alpha$.
Proof. Since $\mathcal{H}(t)=\max \left\{\frac{g^{\prime}(t)}{t}, g^{\prime \prime}(t)\right\}$ we have that $\mathcal{H}(t) t^{2} \leq g^{\prime}(t) t+g^{\prime \prime}(t) t^{2} \quad \forall t \geq 0$. Let $t \geq t_{0} \geq 1$. By the right-hand side of (3.5) and by 3.2 we obtain

$$
g^{\prime \prime}(t) t^{2} \leq K C(1+g(t))^{\frac{1}{2-\alpha}}+K C^{\alpha}(1+g(t))^{\frac{\alpha}{2-\alpha}} t^{-2 \alpha+2}
$$

Let $C_{1}=\max \left\{K C, K C^{\alpha} t_{0}{ }^{-2 \alpha+2}\right\}$. Then we have that for all $t \geq t_{0}$

$$
\begin{equation*}
g^{\prime \prime}(t) t^{2} \leq 2 C_{1}(1+g(t))^{\frac{\alpha}{2-\alpha}} \tag{3.23}
\end{equation*}
$$

On the other hand, if $t \leq t_{0}$ we have

$$
\begin{equation*}
g^{\prime \prime}(t) t^{2} \leq \sup _{0 \leq t \leq t_{0}} g^{\prime \prime}(t) t^{2} \leq t_{0}^{2} \sup _{0 \leq t \leq t_{0}} g^{\prime \prime}(t) \leq C_{t_{0}} \tag{3.24}
\end{equation*}
$$

By putting together (3.23), (3.24) and lemma 3.2, from the definition of $\mathcal{H}(t)$, we obtain the result.

## 4 A-priori estimates

In this section we consider the integral of the Calculus of Variations

$$
\begin{equation*}
F(u)=\int_{\Omega} f(D u) d x \tag{4.1}
\end{equation*}
$$

with $f(D u)=g(|D u|)$, were $g$ satisfies (3.1). We make the following assumption:
Assumption 4.1 There exist two positive constants $N$ and $M$ such that

$$
\begin{equation*}
N|\lambda|^{2} \leq \sum_{i, j, \alpha, \beta} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}}(\xi) \lambda_{i}^{\alpha} \lambda_{j}^{\beta} \leq M|\lambda|^{2}, \quad \forall \lambda, \xi \in \mathbb{R}^{m \times n}, \quad f(\xi)=g(|\xi|) \tag{4.2}
\end{equation*}
$$

This is equivalent to say that both $\frac{g^{\prime}(t)}{t}$ and $g^{\prime \prime}(t)$ are bounded by constants $N, M, \forall t>$ 0 . This assumption allows us to consider $u$ as a function of class $W_{\text {loc }}^{1, \infty}\left(\Omega, \mathbb{R}^{m}\right) \cap$ $W_{\text {loc }}^{2,2}\left(\Omega, \mathbb{R}^{m}\right)$. Similarly in [21], assumption (4.2) will be successively removed. The reason that will make this removal possible relies on the fact that the constants $N$ and $M$ do not enter in the a-priori bound obtained for the $L^{\infty}$-norm of the gradient. We will denote by $B_{\rho}, B_{R}$ balls of radii respectively $\rho$ and $R(\rho<R)$ contained in $\Omega$ and with the same center.

Lemma 4.1 Let $g$ be as in (3.1), satisfying (4.2) and (3.6). Let $u \in W_{l o c}^{1,1}\left(\Omega ; \mathbb{R}^{m}\right)$ be a minimizer of the integral (4.1). Then there exists a constant $C$, which does not depend of $N$ and $M$, such that (the function $\mathcal{H}$ is defined in (3.4))

$$
\|D u\|_{L^{\infty}\left(B_{\rho} ; \mathbb{R}^{m \times n}\right)}^{2-\beta n} \leq \frac{C}{(R-\rho)^{n}} \int_{B_{R}}\left(1+|D u|^{2} \mathcal{H}(|D u|)\right) d x
$$

Proof. Let $u$ be a local minimizer of (4.1). By the left-hand side of (4.2), $u \in$ $W^{1,2}\left(\Omega ; \mathbb{R}^{m}\right)$ and by the right-hand side of (4.2) it satisfies the weak Euler first variation:

$$
\begin{equation*}
\int_{\Omega} \sum_{i, \alpha} f_{\xi_{i}^{\alpha}}(D u) \varphi_{x_{i}}^{\alpha} d x=0, \quad \forall \varphi=\left(\varphi^{\alpha}\right) \in W_{0}^{1,2}\left(\Omega, \mathbb{R}^{m}\right) \tag{4.3}
\end{equation*}
$$

Using some known techniques (see for example ([3]), ([9]), ([18]), ([19]), ([20])) we can prove that $u$ admits second order weak partial derivatives, precisely that $u \in$ $W_{l o c}^{2,2}\left(\Omega ; \mathbb{R}^{m}\right)$ and it satisfies the second variation

$$
\begin{equation*}
\int_{\Omega} \sum_{i, j, \alpha, \beta} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}}(D u) u_{x_{j} x_{k}}^{\beta} \varphi_{x_{i}}^{\alpha} d x=0, \quad \forall k=1,2, \ldots n, \quad \forall \varphi=\left(\varphi^{\alpha}\right) \in W_{0}^{1,2}\left(\Omega, \mathbb{R}^{m}\right) \tag{4.4}
\end{equation*}
$$

For $k \in\{1,2, \ldots, n\}$ we consider $\varphi \in W_{0}^{1,2}\left(\Omega, \mathbb{R}^{m}\right)$ (we do not denote explicitly the dependence on $k$ ) defined by:

$$
\varphi:=\eta^{2} u_{x_{k}} \Phi(|D u|),
$$

where $\eta \in C_{0}^{1}(\Omega)$ and $\Phi:[0,+\infty) \rightarrow[0,+\infty)$ is an increasing bounded Lipschitz continuous function. We plug $\varphi$ in (4.4) and, since

$$
\varphi_{x_{i}}^{\alpha}=2 \eta \eta_{x_{i}} u_{x_{k}}^{\alpha} \Phi(|D u|)+\eta^{2} u_{x_{i} x_{k}}^{\alpha} \Phi(|D u|)+\eta^{2} u_{x_{k}}^{\alpha} \Phi^{\prime}(|D u|)(|D u|)_{x_{i}}
$$

we obtain

$$
\begin{align*}
& \int_{\Omega} 2 \eta \Phi \sum_{i, j, \alpha, \beta} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}} u_{x_{j} x_{k}}^{\beta} u_{x_{k}}^{\alpha} \eta_{x_{i}} d x+ \\
+ & \int_{\Omega} \eta^{2} \Phi \sum_{i, j, \alpha, \beta} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}} u_{x_{j} x_{k}}^{\beta} u_{x_{i} x_{k}}^{\alpha} d x  \tag{4.5}\\
+ & \int_{\Omega} \eta^{2} \Phi^{\prime} \sum_{i, j, \alpha, \beta} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}} u_{x_{j} x_{k}}^{\beta} u_{x_{k}}^{\alpha}(|D u|)_{x_{i}} d x=0 .
\end{align*}
$$

Defining

$$
\begin{align*}
A_{k} & =\int_{\Omega} 2 \eta \Phi \sum_{i, j, \alpha, \beta} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}} u_{x_{j} x_{k}}^{\beta} u_{x_{k}}^{\alpha} \eta_{x_{i}} d x  \tag{4.6}\\
B_{k} & =\int_{\Omega} \eta^{2} \Phi \sum_{i, j, \alpha, \beta} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}} u_{x_{j} x_{k}}^{\beta} u_{x_{i} x_{k}}^{\alpha} d x  \tag{4.7}\\
C_{k} & =\int_{\Omega} \eta^{2} \Phi^{\prime} \sum_{i, j, \alpha, \beta} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}} u_{x_{j} x_{k}}^{\beta} u_{x_{k}}^{\alpha}(|D u|)_{x_{i}} d x \tag{4.8}
\end{align*}
$$

equation (4.5) takes the concise form

$$
\begin{equation*}
A_{k}+B_{k}+C_{k}=0 \tag{4.9}
\end{equation*}
$$

We start estimating the first addendum $A_{k}$ in (4.9) with the inequality $2 a b \leq \frac{1}{2} a^{2}+2 b^{2}$

$$
\begin{align*}
\left|A_{k}\right| & \leq \int_{\Omega} 2 \Phi\left[\eta^{2} \sum_{i, j, \alpha, \beta} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}} u_{x_{j} x_{k}}^{\beta} u_{x_{i} x_{k}}^{\alpha}\right]^{\frac{1}{2}}\left[\sum_{i, j, \alpha, \beta} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}} \eta_{x_{i}} u_{x_{k}}^{\alpha} \eta_{x_{j}} u_{x_{k}}^{\beta}\right]^{\frac{1}{2}} d x  \tag{4.10}\\
& \leq \int_{\Omega} \Phi\left[\frac{\eta^{2}}{2} \sum_{i, j, \alpha, \beta} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}} u_{x_{j} x_{k}}^{\beta} u_{x_{i} x_{k}}^{\alpha}+2 \sum_{i, j, \alpha, \beta} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}} \eta_{x_{i}} u_{x_{k}}^{\alpha} \eta_{x_{j}} u_{x_{k}}^{\beta}\right] d x
\end{align*}
$$

From (4.9) and (4.10) we obtain

$$
\begin{equation*}
\frac{1}{2} B_{k}+C_{k} \leq 2 \int_{\Omega} \Phi(|D u|) \sum_{i, j, \alpha, \beta} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}}(D u) \eta_{x_{i}} u_{x_{k}}^{\alpha} \eta_{x_{j}} u_{x_{k}}^{\beta} d x \tag{4.11}
\end{equation*}
$$

We use the expression of the second derivatives of $f$ in (3.2) to estimate $C_{k}$ in the left-hand side. Since

$$
\begin{equation*}
(|D u|)_{x_{i}}=\frac{1}{|D u|} \sum_{\alpha, k} u_{x_{i} x_{k}}^{\alpha} u_{x_{k}}^{\alpha} \tag{4.12}
\end{equation*}
$$

we obtain

$$
\begin{align*}
& \sum_{k} \sum_{i, j, \alpha, \beta} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}} u_{x_{j} x_{k}}^{\beta} u_{x_{k}}^{\alpha}(|D u|)_{x_{i}}= \\
= & \left(\frac{g^{\prime \prime}}{|D u|^{2}}-\frac{g^{\prime}}{|D u|^{3}}\right) \sum_{k, i, j, \alpha, \beta} u_{x_{i}}^{\alpha} u_{x_{j}}^{\beta} u_{x_{j} x_{k}}^{\beta} u_{x_{k}}^{\alpha}(|D u|)_{x_{i}}+\frac{g^{\prime}}{|D u|} \sum_{k, i, \alpha} u_{x_{i} x_{k}}^{\alpha} u_{x_{k}}^{\alpha}(|D u|)_{x_{i}}= \\
= & \left(\frac{g^{\prime \prime}}{|D u|}-\frac{g^{\prime}}{|D u|^{2}}\right) \sum_{k, i, \alpha} u_{x_{i}}^{\alpha}(|D u|)_{x_{i}} u_{x_{k}}^{\alpha}(|u|)_{x_{k}}+g^{\prime} \sum_{i}(|D u|)_{x_{i}}^{2} \\
= & \left(\frac{g^{\prime \prime}}{|D u|}-\frac{g^{\prime}}{|D u|^{2}}\right) \sum_{\alpha}\left[\sum_{i} u_{x_{i}}^{\alpha}(|D u|)_{x_{i}}\right]^{2}+g^{\prime}|D(|D u|)|^{2} . \tag{4.13}
\end{align*}
$$

Now we recall the definition (4.8) for $C_{k}$. The previous equality shows that

$$
\begin{align*}
\sum_{k} C_{k}= & \int_{\Omega} \eta^{2} \Phi^{\prime}(|D u|)\left\{\left(\frac{g^{\prime \prime}(|D u|)}{|D u|}-\frac{g^{\prime}(|D u|)}{|D u|^{2}}\right)\right.  \tag{4.14}\\
& \left.\cdot \sum_{\alpha}\left[\sum_{i} u_{x_{i}}^{\alpha}(|D u|)_{x_{i}}\right]^{2}+g^{\prime}(|D u|)|D(|D u|)|^{2}\right\} d x
\end{align*}
$$

Now we consider the first term $\frac{1}{2} B_{k}$ in the inequality (4.11). From (3.2) we get

$$
\sum_{i, j, \alpha, \beta} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}}(D u) u_{x_{j} x_{k}}^{\beta} u_{x_{i} x_{k}}^{\alpha}=\left(\frac{g^{\prime \prime}(|D u|)}{|D u|^{2}}-\frac{g^{\prime}(|D u|)}{|D u|^{3}}\right)\left(\sum_{i, \alpha} u_{x_{i} x_{k}}^{\alpha} u_{x_{i}}^{\alpha}\right)^{2}+\frac{g^{\prime}(|D u|)}{|D u|} \sum_{i, \alpha}\left(u_{x_{i} x_{k}}^{\alpha}\right)^{2} .
$$

By (4.12), summing with respect to $k$

$$
\sum_{k} \sum_{i, j, \alpha, \beta} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}}(D u) u_{x_{j} x_{k}}^{\beta} u_{x_{i} x_{k}}^{\alpha}=\left(g^{\prime \prime}(|D u|)-\frac{g^{\prime}(|D u|)}{|D u|}\right)|D(|D u|)|^{2}+\frac{g^{\prime}(|D u|)}{|D u|}\left|D^{2} u\right|^{2}
$$

By the definition (4.7) we can write

$$
\begin{equation*}
\sum_{k} B_{k}=\int_{\Omega} \eta^{2} \Phi(|D u|)\left(\left(g^{\prime \prime}(|D u|)-\frac{g^{\prime}(|D u|)}{|D u|}\right)|D(|D u|)|^{2}+\frac{g^{\prime}(|D u|)}{|D u|}\left|D^{2} u\right|^{2}\right) d x \tag{4.15}
\end{equation*}
$$

By (4.12) and applying the Cauchy-Schwarz inequality we have

$$
|D(|D u|)|^{2}=\sum_{i}(|D u|)_{x_{i}}^{2}=\frac{1}{|D u|^{2}} \sum_{i}\left(\sum_{\alpha, k} u_{x_{i} x_{k}}^{\alpha} u_{x_{k}}^{\alpha}\right)^{2} \leq \sum_{i, \alpha, k}\left(u_{x_{i} x_{k}}^{\alpha}\right)^{2}=\left|D^{2} u\right|^{2}
$$

from which we deduce that

$$
\begin{equation*}
\sum_{k} B_{k} \geq \int_{\Omega} \eta^{2} \Phi(|D u|) g^{\prime \prime}(|D u|)|D(|D u|)|^{2} d x \tag{4.16}
\end{equation*}
$$

Now, we consider $\sum_{k} C_{k}$ in formula (4.14). We can write that

$$
\begin{aligned}
\sum_{k} C_{k} & =\int_{\Omega} \eta^{2} \Phi^{\prime}(|D u|)\left(\frac{g^{\prime \prime}(|D u|)}{|D u|} \sum_{\alpha}\left(\sum_{i} u_{x_{i}}^{\alpha}(|D u|)_{x_{i}}\right)^{2}+g^{\prime}(|D u|)|D(|D u|)|^{2}\right. \\
& \left.-\frac{g^{\prime}(|D u|)}{|D u|^{2}} \sum_{\alpha}\left(\sum_{i} u_{x_{i}}^{\alpha}(|D u|)_{x_{i}}\right)^{2}\right) d x
\end{aligned}
$$

Since, by Cauchy - Schwarz inequality, we get

$$
\sum_{\alpha}\left(\sum_{i} u_{x_{i}}^{\alpha}(|D u|)_{x_{i}}\right)^{2} \leq \sum_{i, \alpha}\left(u_{x_{i}}^{\alpha}\right)^{2} \sum_{i}(|D u|)_{x_{i}}^{2} \leq|D u|^{2}|D(|D u|)|^{2}
$$

then we can conclude that

$$
\begin{equation*}
\sum_{k} C_{k} \geq \int_{\Omega} \eta^{2} \Phi^{\prime}(|D u|) \frac{g^{\prime \prime}(|D u|)}{|D u|} \sum_{\alpha}\left(\sum_{i} u_{x_{i}}^{\alpha}(|D u|)_{x_{i}}\right)^{2} d x \geq 0 \tag{4.17}
\end{equation*}
$$

By using the inequalities obtained for $\sum_{k} B_{k}$ and $\sum_{k} C_{k}$ in (4.16) and (4.17) we obtain from the formula (4.11) where we sum on $k$

$$
\begin{align*}
& \frac{1}{2} \int_{\Omega} \eta^{2} \Phi(|D u|) g^{\prime \prime}(|D u|)|D(|D u|)|^{2} d x \leq \frac{1}{2} \sum_{k} B_{k} \leq \frac{1}{2} \sum_{k} B_{k}+\sum_{k} C_{k} \leq \\
\leq & 2 \int_{\Omega} \Phi(|D u|) \sum_{i, j, \alpha, \beta, k} f_{\xi_{i}^{\alpha} \xi_{j}^{\beta}}(D u) \eta_{x_{i}} u_{x_{k}}^{\alpha} \eta_{x_{j}} u_{x_{k}}^{\beta} d x . \tag{4.18}
\end{align*}
$$

By the right-hand side in (3.3), finally we obtain

$$
\begin{equation*}
\int_{\Omega} \eta^{2} \Phi(|D u|) g^{\prime \prime}(|D u|)|D(|D u|)|^{2} d x \leq 4 \int_{\Omega} \Phi(|D u|) \mathcal{H}(|D u|)|D \eta|^{2}|D u|^{2} d x . \tag{4.19}
\end{equation*}
$$

for every $\Phi:[0,+\infty) \rightarrow[0,+\infty)$, increasing, local Lipschitz continuous function with $\Phi$ and $\Phi^{\prime}$ bounded on $[0,+\infty)$. If we consider a more general $\Phi$ not bounded, with derivative $\Phi^{\prime}$ not bounded too, then we can approximate it by a sequence of functions $\Phi_{r}$, each of them being equal to $\Phi$ in the interval $[0, r]$, and then extended to $[r,+\infty)$ with the constant value $\Phi(r)$. We insert $\Phi(r)$ in (4.19) and we go to the limit as $r \rightarrow+\infty$ by the monotone convergence theorem. So we obtain that (4.19) is true for every $\Phi$ positive, increasing, local Lipschitz continuous function in $[0,+\infty)$. Let us define

$$
\begin{equation*}
G(t)=1+\int_{0}^{t} \sqrt{\Phi(s) g^{\prime \prime}(s)} d s, \quad \forall t \geq 0 \tag{4.20}
\end{equation*}
$$

By Hölder inequality, since function $\Phi$ is increasing and $g^{\prime}(0)=0$, we get

$$
\begin{aligned}
{[G(t)]^{2} } & =\left(1+\int_{0}^{t} \sqrt{\Phi(s) g^{\prime \prime}(s)}\right)^{2} \leq 2+2 \Phi(t) t \int_{0}^{t} g^{\prime \prime}(s) d s \\
& =2+2 \Phi(t) t g^{\prime}(t) \leq 2+2 \Phi(t) \mathcal{H}(t) t^{2}
\end{aligned}
$$

Then we can write the following estimate for the gradient of function $\eta G(|D u|)$

$$
|D(\eta G(|D u|))|^{2}=\left|(D \eta) G(|D u|)+\eta G^{\prime}(|D u|) D(|D u|)\right|^{2}
$$

$$
\begin{gathered}
\leq 2|D \eta|^{2}|G(|D u|)|^{2}+2 \eta^{2}\left|G^{\prime}(|D u|)\right|^{2} \cdot|D(|D u|)|^{2} \\
\leq 4|D \eta|^{2}\left(1+\Phi(|D u|) \mathcal{H}(|D u|)|D u|^{2}\right)+2 \eta^{2} \Phi(|D u|) g^{\prime \prime}(|D u|)|D(|D u|)|^{2}
\end{gathered}
$$

By integrating over $\Omega$ the previous inequality we obtain

$$
\begin{aligned}
& \int_{\Omega}|D(\eta G(|D u|))|^{2} d x \leq \\
\leq & 4 \int_{\Omega}|D \eta|^{2}\left(1+\Phi(|D u|) \mathcal{H}(|D u|)|D u|^{2}\right) d x+2 \int_{\Omega} \eta^{2} \Phi(|D u|) g^{\prime \prime}(|D u|) \mid D(|D u|) d x .
\end{aligned}
$$

Now we use the inequality (4.19) and we get

$$
\begin{equation*}
\int_{\Omega}|D(\eta G(|D u|))|^{2} d x \leq 4 \int_{\Omega}|D \eta|^{2}\left(1+3 \Phi(|D u|) \mathcal{H}(|D u|)|D u|^{2}\right) d x \tag{4.21}
\end{equation*}
$$

As a consequence of (4.2), Du is locally bounded; hence we can apply Sobolev's inequality: there exists a constant $C_{1}$ such that

$$
\begin{equation*}
\left\{\int_{\Omega}[\eta G(|D u|)]^{2^{*}} d x\right\}^{\frac{2}{2^{*}}} \leq C_{1} \int_{\Omega}|D(\eta G(|D u|))|^{2} d x \tag{4.22}
\end{equation*}
$$

Let us define $\Phi(t)=t^{2 \gamma}$, with $\gamma \geq 0$ ( so that $\Phi$ is increasing). Since $g$ satisfies (3.6) we can choose $\delta=2^{*}$ and combining (4.22) and (4.21) we have that there exist constants $C_{3}, C_{4}$ and same $\beta, 0 \leq \beta<\frac{2}{n}$ such that

$$
\begin{align*}
& \int_{\Omega}|D \eta|^{2}\left(1+3 \Phi(|D u|) \mathcal{H}(|D u|)|D u|^{2}\right) d x \geq \frac{1}{4} \int_{\Omega}|D(\eta G(|D u|))|^{2} d x \geq  \tag{4.23}\\
& C_{3}\left\{\int_{\Omega}[\eta G(|D u|)]^{2^{*}} d x\right\}^{\frac{2}{2^{*}}} \geq \frac{C_{4}}{(\gamma+1)^{2}}\left\{\int_{\Omega} \eta^{2^{*}}\left(1+|D u|^{(\gamma+1-\beta) 2^{*}} \mathcal{H}(|D u|)\right) d x\right\}^{\frac{2}{2^{*}}}
\end{align*}
$$

Substituting in the left-hand side of inequality (4.23) the expression of function $\Phi$ we get that there exist a constant $C_{5}$ and same numbers $\beta, 0 \leq \beta<\frac{2}{n}$ such that for every $\gamma \geq 0$

$$
\begin{aligned}
\left\{\int_{\Omega} \eta^{2^{*}}(1\right. & \left.\left.+|D u|^{(\gamma+1-\beta) 2^{*}} \mathcal{H}(|D u|)\right) d x\right\}^{\frac{2}{2^{*}}} \\
& \leq C_{5}(\gamma+1)^{2} \int_{\Omega}|D \eta|^{2}\left(1+|D u|^{2 \gamma} \mathcal{H}(|D u|)|D u|^{2}\right) d x
\end{aligned}
$$

Let the test function $\eta$ be equal to 1 in $B_{\rho}$, with support contained in $B_{R}$ and such that $|D \eta| \leq \frac{2}{(R-\rho)}$. Let us denote by $\delta=2(\gamma+1)$ (note that, since $\gamma \geq 0$, then $\delta \geq 2$ ). We have

$$
\begin{align*}
\left\{\int_{B_{\rho}}(1\right. & \left.\left.+|D u|^{(\delta-2 \beta) \frac{2 *}{2}} \mathcal{H}(|D u|)\right) d x\right\}^{\frac{2}{2^{*}}} \\
& \leq C_{5}\left(\frac{\delta}{R-\rho}\right)^{2} \int_{B_{R}}\left(1+|D u|^{\delta} \mathcal{H}(|D u|)\right) d x \tag{4.24}
\end{align*}
$$

Fixed $\bar{R}$ and $\bar{\rho}$, with $\bar{R}>\bar{\rho}$ we define the decreasing sequence of radii $\left\{\rho_{i}\right\}_{i \geq 0}$

$$
\rho_{i}=\bar{\rho}+\frac{\bar{R}-\bar{\rho}}{2^{i}}, \quad \forall i \geq 0
$$

We observe that $\rho_{0}=\bar{R}>\rho_{i}>\rho_{i+1}>\bar{\rho}$. We define also the increasing sequence of exponents $\left\{\delta_{i}\right\}_{i \geq 0}, \delta_{0}=2, \delta_{i+1}=\left(\delta_{i}-2 \beta\right) \frac{2^{*}}{2}, i \geq 0$, and we rewrite the (4.24) with $R=\rho_{i}, \rho=\rho_{i+1}$ and $\delta=\delta_{i}$. Then we obtain for every $i \geq 0$ :

$$
\begin{align*}
\left\{\int_{B_{\rho_{i+1}}}(1\right. & \left.\left.+|D u|^{\delta_{i+1}} \mathcal{H}(|D u|)\right) d x\right\}^{\frac{2}{2^{*}}} \\
& \leq C_{5}\left(\frac{\delta_{i} 2^{i+1}}{\bar{R}-\bar{\rho}}\right)^{2} \int_{B_{\rho_{i}}}\left(1+|D u|^{\delta_{i}} \mathcal{H}(|D u|)\right) d x \tag{4.25}
\end{align*}
$$

By iterating (4.25) we get

$$
\begin{gather*}
\left\{\int_{B_{\rho_{i+1}}}\left(1+|D u|^{(2-\beta n)\left(\frac{2^{*}}{2}\right)^{i+1}+\beta n} \mathcal{H}(|D u|)\right) d x\right\}^{\left(\frac{2}{2^{*}}\right)^{i+1}} \\
\leq C_{6} \int_{B_{\bar{R}}}\left(1+|D u|^{2} \mathcal{H}(|D u|)\right) d x \tag{4.26}
\end{gather*}
$$

where the exponent in the first integral is given by computing

$$
\delta_{i+1}=2\left(\frac{2^{*}}{2}\right)^{i+1}-2 \beta \sum_{k=1}^{i+1}\left(\frac{2^{*}}{2}\right)^{k}=(2-\beta n)\left(\frac{2^{*}}{2}\right)^{i+1}+\beta n
$$

and

$$
\begin{aligned}
C_{6} & \leq \prod_{k=0}^{+\infty}\left[\frac{C_{5} 8}{(\bar{R}-\bar{\rho})^{2}}\left(2^{*}\right)^{2 k}\right]^{\left(\frac{2}{2^{*}}\right)^{k}}=\left(\left(\frac{C_{5} 8}{(\bar{R}-\bar{\rho})^{2}}\right)^{\sum_{k=0}^{+\infty}\left(\frac{2}{2^{*}}\right)^{k}}\right)\left(2^{*}\right)^{\sum_{k=0}^{+\infty} k\left(\frac{2}{2^{*}}\right)^{k}}= \\
& =\left(\frac{C_{5} 8}{(\bar{R}-\bar{\rho})^{2}}\right)^{\frac{n}{2}} \cdot\left(2^{*}\right)^{\frac{n(n-2)}{2}}=\frac{C_{7}}{(\bar{R}-\bar{\rho})^{n}},
\end{aligned}
$$

for every $n \geq 3$; otherwise, if $n=2$, then for every $\epsilon>0$ we can choose $2^{*}$ so that $C_{6}=\frac{C_{7}}{(\bar{R}-\bar{\rho})^{2+\epsilon}}$ for some constant $C_{7}$. Now, we observe that the function $1+t^{\alpha} \mathcal{H}(t) \geq$ $1+t^{\alpha-1} g^{\prime}(t)$, since $\mathcal{H}(t) \geq \frac{g^{\prime}(t)}{t}$ for every $t>0$. Now, if $t \geq 1$, since $g^{\prime}(t)$ is increasing we have $1+t^{\alpha-1} g^{\prime}(t) \geq t^{\alpha-1} g^{\prime}(1)$ and, if $t \leq 1$ we have $1+t^{\alpha-1} g^{\prime}(t) \geq 1 \geq t^{\alpha-1}$. Hence, we can write

$$
\begin{align*}
&\left\{\int_{B_{\bar{\rho}}}|D u|^{\left(2-\beta n+\frac{\beta n-1}{\left(\frac{2^{*}}{2}\right)^{i+1}}\right)\left(\frac{2^{*}}{2}\right)^{i+1}} d x\right\}^{\left(\frac{2}{2^{*}}\right)^{i+1}} \\
& \leq \frac{C_{7}}{(\bar{R}-\bar{\rho})^{n}} \int_{B_{\bar{R}}}\left(1+|D u|^{2} \mathcal{H}(|D u|)\right) d x \tag{4.27}
\end{align*}
$$

Finally we go to the limit as $i \rightarrow+\infty$ and we obtain

$$
\begin{aligned}
& \leq \frac{C_{7}}{(\bar{R}-\bar{\rho})^{n}} \int_{B_{\bar{R}}}\left(1+|D u|^{2} \mathcal{H}(|D u|)\right) d x \text {. }
\end{aligned}
$$

Lemma 4.2 Let $g$ be as in (3.1). Let us assume that $g$ satisfies (4.2) and (3.5). Let $u \in W_{l o c}^{1,1}\left(\Omega ; \mathbb{R}^{m}\right)$ be a minimizer of the integral (4.1). Then, for every $\epsilon>0$ and for every $\rho, R(0<\rho<R)$, there exists a constant $C=C(n, \epsilon, \rho, R)$ such that

$$
\int_{B_{\rho}}\left(1+|D u|^{2} \mathcal{H}(D u)\right) d x \leq C\left\{\int_{B_{R}}(1+g|D u|) d x\right\}^{\frac{1}{1-\beta}+\epsilon}
$$

the constant $C$ depends also on $g\left(t_{0}\right), g^{\prime}\left(t_{0}\right), K, H$, $\sup _{0 \leq t \leq t_{0}} g^{\prime \prime}(t), \inf _{0 \leq t \leq t_{0}} g^{\prime \prime}(t)$, but it does not depend on the constants $N$ and $M$ in (4.2).

Proof. In Lemma 3.1 we considered parameters $\alpha$ and $\gamma$ such that $\alpha \in\left(1, \frac{n}{n-1}\right]$ and $\gamma \geq 0$. Here we restrict ourselves to the case $1<\alpha \leq \frac{2 n}{2 n-1}=1+\frac{1}{2 n-1}$ and $\gamma=0$. Then (3.6) holds for any $\delta \in\left[\frac{2 \alpha}{2-\alpha}, 2^{*}\right]$. We define $\nu=\frac{2^{*}}{\delta}$, so that $\nu \in\left[1,2^{*} \frac{2-\alpha}{2 \alpha}\right]$. The condition $\beta<\frac{2}{n}$ is equivalent to $1<(1-\beta) \frac{2^{*}}{2}$; therefore it is possible to limit $\nu$ (and $\delta$ ) to satisfy the conditions $1<\nu<(1-\beta) \frac{2^{*}}{2}$ too. Finally, since $\beta>\frac{1}{n}$ we have $\alpha \leq \frac{2 n}{2 n-1}<\frac{2}{2-\beta}$ and this implies $1-\beta<\frac{2-\alpha}{\alpha}$. Thus

$$
\nu \in\left[1,(1-\beta) \frac{2^{*}}{2}\right] \Longrightarrow \nu \in\left[1,2^{*} \frac{2-\alpha}{2 \alpha}\right] \Leftrightarrow \delta \in\left[\frac{2 \alpha}{2-\alpha}, 2^{*}\right]
$$

so that the parameter $\delta$ satisfy the condition of Lemma 3.1. Therefore there exists a constant $C_{1}$ (we still denote by $C_{1}, C_{2}$, etc.. the constants in this proof) such that

$$
(G(t))^{2^{*}}=\left[\left(1+\int_{0}^{t} \sqrt{g^{\prime \prime}(s)} d s\right)^{\frac{2^{*}}{\nu}}\right]^{\nu} \geq C_{2}\left[1+t^{(1-\beta) \frac{2^{*}}{\nu}} \mathcal{H}(t)\right]^{\nu}
$$

Under the notations of the previous Lemma 4.1, let us consider again the estimates (4.23) with $\phi$ identically equal to 1 (or, equivalently, with $\gamma=0$ ); we have

$$
\left\{\int_{\Omega}(\eta G(|D u|))^{2^{*}} d x\right\}^{\frac{2}{2^{*}}} \leq 4 C_{2} \int_{\Omega}|D \eta|^{2}\left(1+3 \mathcal{H}(|D u|)|D u|^{2}\right) d x
$$

and thus

$$
\begin{equation*}
\left\{\int_{\Omega} \eta^{2^{*}}\left[1+|D u|^{(1-\beta) \frac{2^{*}}{\nu}} \mathcal{H}(|D u|)\right]^{\nu} d x\right\}^{\frac{2}{2^{*}}} \leq C_{3} \int_{\Omega}|D \eta|^{2}\left(1+\mathcal{H}(|D u|)|D u|^{2}\right) d x \tag{4.28}
\end{equation*}
$$

Since $\nu<(1-\beta) \frac{2^{*}}{2}$, we have $(1-\beta) \frac{2^{*}}{\nu}>2$. Under the notation $V=V(x)=1+$ $|D u|^{2} \mathcal{H}(|D u|)$ (4.28) becomes

$$
\begin{equation*}
\left\{\int_{\Omega} \eta^{2^{*}} V^{\nu} d x\right\}^{\frac{2}{2^{*}}} \leq C_{3} \int_{\Omega}|D \eta|^{2} V d x \tag{4.29}
\end{equation*}
$$

As in the previous Lemma (4.1) we consider a test function $\eta$ equal to 1 on $B_{\rho}$ with support contained in $B_{R}$ and such that $|D \eta| \leq \frac{2}{R-\rho}$, we obtain

$$
\begin{equation*}
\left\{\int_{B_{\rho}} V^{\nu} d x\right\}^{\frac{2}{2^{*}}} \leq \frac{4 C_{4}}{(R-\rho)^{2}} \int_{B_{R}} V d x \tag{4.30}
\end{equation*}
$$

Let $\gamma>\frac{2^{*}}{2}$. By Holder inequality we have

$$
\begin{equation*}
\left\{\int_{B_{\rho}} V^{\nu} d x\right\}^{\frac{2}{2^{*}}} \leq \frac{4 C_{4}}{(R-\rho)^{2}} \int_{B_{R}} V^{\frac{\nu}{\gamma}} V^{1-\frac{\nu}{\gamma}} d x \leq \frac{4 C_{4}}{(R-\rho)^{2}}\left\{\int_{B_{R}} V^{\nu} d x\right\}^{\frac{1}{\gamma}}\left\{\int_{B_{R}} V^{\frac{\gamma-\nu}{\gamma-1}} d x\right\}^{\frac{\gamma-1}{\gamma}} \tag{4.31}
\end{equation*}
$$

Let be $R_{0}$ and $\rho_{0}$ fixed. For any $i \in \mathbb{N}$ we consider (4.31) with $R=\rho_{i}$ and $\rho=\rho_{i-1}$, where $\rho_{i}=R_{0}-\frac{R_{0}-\rho_{0}}{2^{i}}$. By iterating (4.31), since $R-\rho=\frac{R_{0}-\rho_{0}}{2^{i}}$, similarly to the computation in [21], page 19 we can write

$$
\begin{equation*}
\int_{B_{\rho_{0}}} V^{\nu} d x \leq\left\{\int_{B_{\rho_{i}}} V^{\nu} d x\right\}^{\left(\frac{2^{*}}{2 \gamma}\right)^{i}} C_{5}\left\{\frac{1}{\left(R_{0}-\rho_{0}\right)^{2}}\right\}^{\left(\frac{2^{*} \gamma}{2 \gamma-2}\right)^{i}}\left\{\int_{B_{\rho_{0}}} V^{\frac{\gamma-\nu}{\gamma-1}} d x\right\}^{\frac{2^{*}(\gamma-1)}{2 \gamma-2^{*}}} . \tag{4.32}
\end{equation*}
$$

Since $\frac{\gamma-\nu}{\gamma-1}<1$ we can apply Lemma (3.3) with $\eta=\frac{\gamma-1}{\gamma-\nu}$ and we obtain

$$
\int_{B_{\rho}} V^{\nu} d x \leq\left\{\int_{B_{\rho_{i}}} V^{\nu} d x\right\}^{\left(\frac{2^{*}}{2 \gamma}\right)^{i}} C_{5}\left\{\frac{1}{\left(R_{0}-\rho_{0}\right)^{2}}\right\}^{\frac{2^{*} \gamma}{2 \gamma-2^{*}}}\left\{\int_{B_{\rho_{0}}}[1+g(|D u|)] d x\right\}^{\frac{2^{*}(\gamma-1)}{2 \gamma-2^{*}}}
$$

In the limit as $i \rightarrow+\infty$ we get

$$
\int_{B_{\rho_{0}}} V^{\nu} d x \leq C_{6}\left\{\frac{1}{\left(R_{0}-\rho_{0}\right)^{2}}\right\}^{\frac{2^{*} \gamma}{2 \gamma-2^{*}}}\left\{\int_{B_{R_{0}}}[1+g(|D u|)] d x\right\}^{\frac{2^{*}(\gamma-1)}{2 \gamma-2^{*}}}
$$

Finally

$$
\begin{align*}
\int_{B_{\rho_{0}}} V d x & \leq \operatorname{meas}\left\{B_{\rho_{0}}\right\}^{1-\frac{1}{\nu}}\left\{\int_{B_{\rho_{0}}} V^{\nu} d x\right\}^{\frac{1}{\nu}} \\
& \leq C_{7}\left\{\frac{1}{\left(R_{0}-\rho_{0}\right)^{2}}\right\}^{\frac{2^{*} \gamma}{\left(2 \gamma-2^{*}\right) \nu}}\left\{\int_{B_{R_{0}}}[1+g(|D u|)] d x\right\}^{\frac{2^{*}(\gamma-1)}{\left(2 \gamma-2^{*}\right) \nu}} \tag{4.33}
\end{align*}
$$

As $\nu \rightarrow(1-\beta) \frac{2^{*}}{2}$ and $\gamma \rightarrow+\infty$ the two exponents in (4.33) converge to $\frac{1}{1-\beta}$ and we have the result.
By combining together Lemma (3.1), Lemma (4.1) and Lemma (4.2) we proved the following theorem.

Theorem 4.1 Let $g$ be as in (3.1). Suppose that $g$ satisfies (4.2) and (3.5). Let $u \in W_{\text {loc }}^{1,1}\left(\Omega ; \mathbb{R}^{m}\right)$ be a minimizer of the integral (4.1). Then $u \in W_{\text {loc }}^{1, \infty}\left(\Omega ; \mathbb{R}^{m}\right)$ and for every $\epsilon>0$ and for every $\rho, R(0<\rho<R)$, there exists a constant $C=C(n, \epsilon, \rho, R)$ such that

$$
\|D u\|_{L^{\infty}\left(B \rho ; \mathbb{R}^{m \times n}\right)}^{2-\beta n} \leq C\left\{\int_{B_{R}}(1+g(|D u|)) d x\right\}^{\frac{1}{1-\beta}+\epsilon}
$$

the constant $C$ depends also on $H, K$, $\sup _{0 \leq t \leq t_{0}} g^{\prime \prime}(t)$, but does not depend on the constants $N$ and $M$ in (4.2).

## 5 The approximating regular problems

Let us consider a function $g$ with the properties described in (3.1). Now we consider the function $\frac{g^{\prime}(t)}{t}$. It is possible to have one and only one of the following three cases:
i) There exists a sequence $\left\{t_{n}\right\}, \lim _{n \rightarrow+\infty} t_{n}=+\infty$ such that $\frac{g^{\prime}\left(t_{n}\right)}{t_{n}}=1$
ii) There exists $T$ such that for all $t \geq T$ it follows that $\frac{g^{\prime}(t)}{t}>1$
iii) There exists $T$ such that for all $t \geq T$ it follows that $\frac{g^{\prime}(t)}{t}<1$

Let $\bar{t}=\inf \left\{t>0: \frac{g^{\prime}(t)}{t}>0\right\}$; up to a rescaling we can assume $0 \leq \bar{t}<1 \leq t_{0}$. We consider a sequence $\epsilon_{n}, \lim _{n \rightarrow+\infty} \epsilon_{n}=0$, in the following way. In case i) we put $\epsilon_{n}=\frac{1}{t_{n}}$, in case ii) or iii) we consider any sequence $\epsilon_{n} \rightarrow 0$, with $\frac{1}{\epsilon_{n}} \geq T$. It is obvious that we
can choose n sufficiently large such that $\bar{t}+\epsilon_{n}<1$ and $\frac{1}{\epsilon_{n}} \geq \max \left\{T, \bar{t}+\epsilon_{n}\right\}$. Now we define the function

$$
g_{\epsilon_{n}}^{\prime}(t)=\left\{\begin{array}{l}
\frac{g^{\prime}\left(\bar{t}+\epsilon_{n}\right)}{\bar{t}+\epsilon_{n}} t, \quad 0 \leq t \leq \bar{t}+\epsilon_{n}  \tag{5.1}\\
g^{\prime}(t), \quad \bar{t}+\epsilon_{n}<t \leq \frac{1}{\epsilon_{n}} \\
\min \left\{\epsilon_{n} g^{\prime}\left(\frac{1}{\epsilon_{n}}\right) t, g^{\prime}(t)+\epsilon_{n} t-1\right\}, \quad t>\frac{1}{\epsilon_{n}}
\end{array}\right.
$$

Then obviously we can define

$$
\begin{equation*}
g_{\epsilon_{n}}(t)=\int_{0}^{t} g_{\epsilon_{n}}^{\prime}(s) d s \tag{5.2}
\end{equation*}
$$

The function $g_{\epsilon_{n}}(t)$ results to be a convex function of class $C^{1}([0,+\infty))$, satisfying (3.1) and (4.2) with suitable constants $N\left(\epsilon_{n}\right)$ and $M\left(\epsilon_{n}\right)$.

Lemma 5.1 Let $g$ be as in (3.1) satisfying the left-hand side of (3.5). Let $g_{\epsilon_{n}}(t)$ defined in (5.2). Then there exists a constant $H_{1}>0$ such that we have

$$
\begin{equation*}
H_{1} t^{-2 \beta}\left[\left(\frac{g_{\epsilon_{n}}^{\prime}(t)}{t}\right)^{\frac{2}{2 *}}+\frac{g_{\epsilon_{n}}^{\prime}(t)}{t}\right] \leq g_{\epsilon_{n}}^{\prime \prime}(t), \quad \forall t \geq t_{0} \tag{5.3}
\end{equation*}
$$

Proof. Let $\bar{t}+\epsilon_{n}<1 \leq t_{0}$ and $t \geq t_{0}$.

1) If $\bar{t}+\epsilon_{n}<t \leq \frac{1}{\epsilon_{n}}$ then (5.3) holds because $g_{\epsilon_{n}}^{\prime}(t)=g^{\prime}(t)$ and $g_{\epsilon_{n}}^{\prime \prime}(t)=g^{\prime \prime}(t)$.
2) Let $t>\frac{1}{\epsilon_{n}}$.

2a) If $g_{\epsilon_{n}}^{\prime}(t)=\epsilon_{n} g^{\prime}\left(\frac{1}{\epsilon_{n}}\right) t$ then $g_{\epsilon_{n}}^{\prime \prime}(t)=\epsilon_{n} g^{\prime}\left(\frac{1}{\epsilon_{n}}\right)$ and we have

$$
t^{-2 \beta}\left(\epsilon_{n} g^{\prime}\left(\frac{1}{\epsilon_{n}}\right)\right)^{\frac{2}{2^{*}}}+t^{-2 \beta} \epsilon_{n} g^{\prime}\left(\frac{1}{\epsilon_{n}}\right) \leq \epsilon_{n}^{2 \beta+\frac{2}{2^{*}}}\left[\frac{g^{\prime}\left(\frac{1}{\epsilon_{n}}\right)}{g^{\prime}\left(t_{0}\right)}\right]^{\frac{2}{2^{*}}}\left(g^{\prime}\left(t_{0}\right)\right)^{\frac{2}{2^{*}}}+\epsilon_{n} g^{\prime}\left(\frac{1}{\epsilon_{n}}\right)
$$

Since $2 \beta+\frac{2}{2^{*}}>1$ and $\epsilon_{n} \leq 1$ we have $\epsilon_{n}{ }^{2 \beta+\frac{2}{2^{*}}} \leq \epsilon_{n}$; moreover the monotonicity of function $g^{\prime}(t)$ get $\frac{g^{\prime}\left(\frac{1}{\epsilon_{n}}\right)}{g^{\prime}\left(t_{0}\right)} \geq 1$. As a consequence we can write
$t^{-2 \beta}\left[\left(\frac{g_{\epsilon_{n}}^{\prime}(t)}{t}\right)^{\frac{2}{2^{*}}}+\frac{g_{\epsilon_{n}}^{\prime}(t)}{t}\right] \leq\left(\left(g^{\prime}\left(t_{0}\right)\right)^{\frac{2}{2^{*}-1}}+1\right) \epsilon_{n} g^{\prime}\left(\frac{1}{\epsilon_{n}}\right)=\left(\left(g^{\prime}\left(t_{0}\right)\right)^{\frac{2}{2^{*}}-1}+1\right) g_{\epsilon_{n}}^{\prime \prime}(t)$,
i.e. (5.3) holds with $H_{1} \leq\left(\left(g^{\prime}\left(t_{0}\right)\right)^{\frac{2}{2^{*}-1}}+1\right)^{-1}$.

2b) Let $g_{\epsilon_{n}}^{\prime}(t)=g^{\prime}(t)+\epsilon_{n} t-1$. Then

$$
\frac{g^{\prime}(t)}{t} \leq \frac{g^{\prime}(t)}{t}+\epsilon_{n}-\frac{1}{t}=\frac{g_{\epsilon_{n}}^{\prime}(t)}{t} \leq \epsilon_{n} g^{\prime}\left(\frac{1}{\epsilon_{n}}\right) .
$$

If we are in case i) or iii), then we have as a consequence $\frac{g^{\prime}(t)}{t} \leq 1$. Hence by the left-hand side of (3.5) we can write

$$
\begin{gather*}
t^{-2 \beta}\left[\left(\frac{g_{\epsilon_{n}}^{\prime}(t)}{t}\right)^{\frac{2}{2^{*}}}+\frac{g_{\epsilon_{n}}^{\prime}(t)}{t}\right] \leq 2 t^{-2 \beta}\left(\frac{g_{\epsilon_{n}}^{\prime}(t)}{t}\right)^{\frac{2}{2^{*}}}=2 t^{-2 \beta}\left(\frac{g^{\prime}(t)}{t}+\epsilon_{n}-\frac{1}{t}\right)^{\frac{2}{2^{*}}} \\
\leq 2 t^{-2 \beta}\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{2}{2^{*}}}+2 t^{-2 \beta} \epsilon_{n}^{\frac{2}{2^{*}}} \leq \frac{2}{H} g^{\prime \prime}(t)+2 \epsilon_{n}^{\frac{2}{2^{*}}+2 \beta} \tag{5.4}
\end{gather*}
$$

Since the exponent $\frac{2}{2^{*}}+2 \beta>1$ and $\epsilon_{n}<1$, then

$$
\begin{equation*}
\frac{2}{H} g^{\prime \prime}(t)+2 \epsilon_{n}^{\frac{2}{\pi^{2}+2 \beta}}<\frac{2}{H} g^{\prime \prime}(t)+2 \epsilon_{n}<\left(2+\frac{2}{H}\right)\left(g^{\prime \prime}(t)+\epsilon_{n}\right)=\left(2+\frac{2}{H}\right) g_{\epsilon_{n}}^{\prime \prime}(t) \tag{5.5}
\end{equation*}
$$

By (5.4) and (5.5) we have the estimate in (5.3) with $H_{1} \leq\left(2+\frac{2}{H}\right)^{-1}$.
If we are in case ii) then $\frac{g^{\prime}(t)}{t}>1$ and again by the left-hand side of (3.5) we obtain

$$
\begin{gathered}
t^{-2 \beta}\left[\left(\frac{g_{\epsilon_{n}}^{\prime}(t)}{t}\right)^{\frac{2}{2^{*}}}+\frac{g_{\epsilon_{n}}^{\prime}(t)}{t}\right] \leq 2 t^{-2 \beta} \frac{g_{\epsilon_{n}}^{\prime}(t)}{t}=2 t^{-2 \beta}\left(\frac{g_{\epsilon_{n}}^{\prime}(t)}{t}+\epsilon_{n}-\frac{1}{t}\right) \\
\leq 2\left(t^{-2 \beta} \frac{g^{\prime}(t)}{t}+\epsilon_{n}\right) \leq\left(2+\frac{2}{H}\right)\left(g^{\prime \prime}(t)+\epsilon_{n}\right)
\end{gathered}
$$

This last inequality completes the proof.

Lemma 5.2 Let $g$ be as in (3.1) satisfying the right-hand side of (3.5). Let $g_{\epsilon_{n}}(t)$ defined in (5.2). Then there exists a constant $K_{1}>0$ such that for any $\alpha>1$ we have

$$
\begin{equation*}
g_{\epsilon_{n}}^{\prime \prime}(t) \leq K_{1}\left[\frac{g_{\epsilon_{n}}^{\prime}(t)}{t}+\left(\frac{g_{\epsilon_{n}}^{\prime}(t)}{t}\right)^{\alpha}\right], \quad \forall t \geq t_{0} . \tag{5.6}
\end{equation*}
$$

Proof. Let $\bar{t}+\epsilon_{n}<1 \leq t_{0}$ and $t \geq t_{0}$.

1) If $\bar{t}+\epsilon_{n}<t \leq \frac{1}{\epsilon_{n}}$ then the (5.6) holds because $g_{\epsilon_{n}}^{\prime}(t)=g^{\prime}(t)$ and $g_{\epsilon_{n}}^{\prime \prime}(t)=g^{\prime \prime}(t)$.
2) Let $t>\frac{1}{\epsilon_{n}}$.

2a) If $g_{\epsilon_{n}}^{\prime}(t)=\epsilon_{n} g^{\prime}\left(\frac{1}{\epsilon_{n}}\right) t$, then $g_{\epsilon_{n}}^{\prime \prime}(t)=\epsilon_{n} g^{\prime}\left(\frac{1}{\epsilon_{n}}\right)$ and (5.6) is obviously satisfied.

2b) Let $g_{\epsilon_{n}}^{\prime}(t)=g^{\prime}(t)+\epsilon_{n} t-1$ then $g_{\epsilon_{n}}^{\prime \prime}(t)=g^{\prime \prime}(t)+\epsilon_{n}$ and

$$
\frac{g^{\prime}(t)}{t} \leq \frac{g^{\prime}(t)}{t}+\epsilon_{n}-\frac{1}{t} \leq \epsilon_{n} g^{\prime}\left(\frac{1}{\epsilon_{n}}\right) .
$$

If we are in case i) or iii), then we have as a consequence $\frac{g^{\prime}(t)}{t} \leq 1$. By the right-hand side of (3.5) we can write

$$
\begin{equation*}
g_{\epsilon_{n}}^{\prime \prime}(t)=g^{\prime \prime}(t)+\epsilon_{n} \leq 2 K \frac{g^{\prime}(t)}{t}+\epsilon_{n} \leq 2 K\left(\frac{g^{\prime}(t)}{t}+\epsilon_{n}\right) \tag{5.7}
\end{equation*}
$$

Since $g^{\prime}(t)$ is an increasing function, we have

$$
\begin{align*}
& g_{\epsilon_{n}}^{\prime \prime}(t) \leq 2 K\left(\frac{g^{\prime}(t)}{t}+\epsilon_{n}+\left(\frac{1+g^{\prime}\left(t_{0}\right)}{g^{\prime}\left(t_{0}\right)}\right) \frac{g^{\prime}(t)}{t}-\frac{1}{t}\right) \\
& \quad \leq 4 K\left(\frac{1+g^{\prime}\left(t_{0}\right)}{g^{\prime}\left(t_{0}\right)}\right)\left(\frac{g^{\prime}(t)}{t}+\epsilon_{n}-\frac{1}{t}\right)=4 K\left(\frac{1+g^{\prime}\left(t_{0}\right)}{g^{\prime}\left(t_{0}\right)}\right) \frac{g_{\epsilon_{n}}^{\prime}(t)}{t} \tag{5.8}
\end{align*}
$$

i.e. (5.6) with $K_{1} \geq 4 K\left(\frac{1+g^{\prime}\left(t_{0}\right)}{g^{\prime}\left(t_{0}\right)}\right)$.

If case ii) is realized, then $\frac{g^{\prime}(t)}{t}>1$ and we can write

$$
\left(\frac{g_{\epsilon_{n}}^{\prime}(t)}{t}\right)^{\alpha}=\left(\frac{g^{\prime}(t)}{t}+\epsilon_{n}-\frac{1}{t}\right)^{\alpha} \geq \frac{1}{2^{\alpha}}\left(\frac{g^{\prime}(t)}{t}+\epsilon_{n}\right)^{\alpha}=\frac{1}{2^{\alpha}}\left(\frac{g^{\prime}(t)}{t}\right)^{\alpha}\left(1+\frac{\epsilon_{n}}{\frac{g^{\prime}(t)}{t}}\right)^{\alpha}
$$

Since

$$
\left(1+\frac{\epsilon_{n}}{\frac{g^{\prime}(t)}{t}}\right)^{\alpha} \geq 1+\alpha \frac{\epsilon_{n}}{\frac{g^{\prime}(t)}{t}}
$$

we can write

$$
\begin{equation*}
\left(\frac{g_{\epsilon_{n}}^{\prime}(t)}{t}\right)^{\alpha} \geq \frac{1}{2^{\alpha}}\left[\left(\frac{g^{\prime}(t)}{t}\right)^{\alpha}+\epsilon_{n}\right] \geq \frac{1}{2^{\alpha+1} K}\left(g^{\prime \prime}(t)+\epsilon_{n}\right)=\frac{1}{2^{\alpha} K} g_{\epsilon_{n}}^{\prime \prime}(t) \tag{5.9}
\end{equation*}
$$

i.e. (5.6) with $K_{1} \geq K 2^{\alpha+1}$. Combining (5.8) and (5.9) we obtain the result.

Lemma 5.3 Let $g$ be as in (3.1). Let $g_{\epsilon_{n}}(t)$ be defined in (5.2). Then there exists a constant $C$ such that

$$
\begin{equation*}
g_{\epsilon_{n}}(t) \leq C(1+g(t))+\epsilon_{n} t^{2}, \quad \forall t \geq 0 . \tag{5.10}
\end{equation*}
$$

Proof. Let $\bar{t}+\epsilon_{n}<1$ and $0 \leq t \leq \bar{t}+\epsilon_{n}$. We have

$$
\begin{equation*}
g_{\epsilon_{n}}(t)=\frac{g^{\prime}\left(\bar{t}+\epsilon_{n}\right)}{\bar{t}+\epsilon_{n}} \frac{t^{2}}{2} \leq \frac{1}{2} \frac{g^{\prime}(1)}{\bar{t}}, \tag{5.11}
\end{equation*}
$$

If $\bar{t}+\epsilon_{n}<t \leq \frac{1}{\epsilon_{n}}$ we have

$$
\begin{equation*}
g_{\epsilon_{n}}(t)=g(t)-g\left(\bar{t}+\epsilon_{n}\right)+\frac{g^{\prime}\left(\bar{t}+\epsilon_{n}\right)\left(\bar{t}+\epsilon_{n}\right)}{2} \leq g(t)+\frac{1}{2} g^{\prime}(1) \tag{5.12}
\end{equation*}
$$

If $t>\frac{1}{\epsilon_{n}}$ we have $g_{\epsilon_{n}}^{\prime}(t) \leq g^{\prime}(t)+\epsilon_{n} t$ from which

$$
\begin{equation*}
g_{\epsilon_{n}}(t) \leq g\left(t_{0}\right)+\int_{t_{0}}^{t}\left(g^{\prime}(s)+\epsilon_{n} s\right) d s \leq g\left(t_{0}\right)+\int_{0}^{t}\left(g^{\prime}(s)+\epsilon_{n} s\right) d s=g\left(t_{0}\right)+g(t)+\frac{\epsilon_{n} t^{2}}{2} \tag{5.13}
\end{equation*}
$$

By (5.11), (5.12) and (5.13) we obtain the result with the constant

$$
C \geq \max \left\{\frac{1}{2} g^{\prime}(1), g\left(t_{0}\right), \frac{1}{2} \frac{g^{\prime}(1)}{\bar{t}}\right\}
$$

## 6 Passage to the limit

Let us consider for every $\epsilon_{n}$ ( $\epsilon_{n}$ is the sequence defined in the previous section 5) the sequence of integral functionals

$$
\begin{equation*}
F_{\epsilon_{n}}(v)=\int_{\Omega} g_{\epsilon_{n}}(|D v|) d x \tag{6.1}
\end{equation*}
$$

where $g_{\epsilon_{n}}(t)$ is defined through its derivative $g_{\epsilon_{n}}^{\prime}(t)$ by (5.1) and (5.2). Let $u \in$ $W_{l o c}^{1,1}\left(\Omega ; \mathbb{R}^{m}\right)$ be a local minimizer of the integral (4.1), i.e. $g(|D u|) \in L_{l o c}^{1}(\Omega)$ and $F(u) \leq F(u+\phi)$ for every $\phi \in C_{0}^{1}\left(\Omega ; \mathbb{R}^{m}\right)$. Let $B_{R}$ be a ball of radius $R$ such that $B_{2 R} \subset \subset \Omega$ and let $0<\sigma<\min \{1, R\}$. We indicate by $u_{\sigma}$ a sequence of smooth functions defined from $u$ by means of standard mollifiers. Then $u_{\sigma} \in W^{1,2}\left(B_{R} ; \mathbb{R}^{m}\right)$. Let $u_{\epsilon_{n}, \sigma}$ be a minimizer of the integral $F_{\epsilon_{n}}(v)$ in (6.1) that satisfies the Dirichlet condition $u_{\epsilon_{n}, \sigma}=u_{\sigma}$ on the boundary $\partial B_{R}$, i.e., since $F_{\epsilon_{n}}$ has a quadratic growth,

$$
\begin{equation*}
\int_{B_{R}} g_{\epsilon_{n}}\left(\left|D u_{\epsilon_{n}, \sigma}\right|\right) d x \leq \int_{B_{R}} g_{\epsilon_{n}}(|D v|) d x, \quad \forall v \in W_{0}^{1,2}\left(B_{R} ; \mathbb{R}^{m}\right)+u_{\sigma} \tag{6.2}
\end{equation*}
$$

By results of previous section 5 , for every $\epsilon_{n}, g_{\epsilon_{n}}$ satisfies conditions (3.1), (4.2) (with suitable constants $N\left(\epsilon_{n}\right)$ and $\left.M\left(\epsilon_{n}\right)\right)$ and (3.5) with constants $H$ and $K$ not depending on $\epsilon_{n}$. Therefore we can apply to $g_{\epsilon_{n}}$ the a-priori estimate obtained in Theorem 4.1 obtaining that for every $\epsilon_{n}$ and for every ball $B_{\rho}$ of radius $\rho<R$ there exists a constant $C_{1}$ (independent on $N, M, \epsilon_{n}, \sigma$ ) such that, for some constants $\beta, \frac{1}{n}<\beta<\frac{2}{n}$ we have

$$
\begin{equation*}
\left\|D u_{\epsilon_{n}, \sigma}\right\|_{L^{\infty}\left(B \rho ; \mathbb{R}^{m \times n}\right)}^{2-\beta n} \leq C_{1}\left\{\int_{B_{R}}\left(1+g_{\epsilon_{n}}\left(\left|D u_{\epsilon_{n}, \sigma}\right|\right)\right) d x\right\}^{\frac{1}{1-\beta}+\epsilon} \tag{6.3}
\end{equation*}
$$

By the minimality of $u_{\epsilon_{n}, \sigma}$ we can write that

$$
\begin{equation*}
\int_{B_{R}} g_{\epsilon_{n}}\left(\left|D u_{\epsilon_{n}, \sigma}\right|\right) d x \leq \int_{B_{R}} g_{\epsilon_{n}}\left(\left|D u_{\sigma}\right|\right) d x \tag{6.4}
\end{equation*}
$$

and by (5.10) and the properties of mollifiers we obtain

$$
\begin{array}{r}
\int_{B_{R}} g_{\epsilon_{n}}\left(\left|D u_{\sigma}\right|\right) d x \leq C_{2}\left\{\int_{B_{R}}\left(1+g\left(\left|D u_{\sigma}\right|\right)\right) d x+\epsilon_{n} \int_{B_{R}}\left|D u_{\sigma}\right|^{2} d x\right\} \\
\leq C_{2}\left\{\int_{B_{R+\sigma}}(1+g(|D u|)) d x+\epsilon_{n} \int_{B_{R}}\left|D u_{\sigma}\right|^{2} d x\right\} \leq C_{3}(\sigma) \tag{6.5}
\end{array}
$$

From this chain of inequalities and (6.3) we obtain as a consequence

$$
\begin{equation*}
\left\|D u_{\epsilon_{n}, \sigma}\right\|_{L^{\infty}\left(B_{\rho} ; \mathbb{R}^{m \times n}\right)}^{2-\beta n} \leq C_{4}\left\{\int_{B_{R+\sigma}}(1+g(|D u|)) d x+\epsilon_{n} \int_{B_{R}}\left|D u_{\sigma}\right|^{2} d x\right\}^{\frac{1}{1-\beta}+\epsilon} \leq C_{5}(\sigma) \tag{6.6}
\end{equation*}
$$

Then for every fixed $\sigma,\left|D u_{\epsilon_{n}, \sigma}\right|$ is equibounded with respect to $\epsilon_{n}$. Hence, up to a subsequence, $u_{\epsilon_{n}, \sigma}$ converges in the weak ${ }^{*}$ topology of $W^{1, \infty}\left(B_{\rho} ; \mathbb{R}^{m \times n}\right)$ to a function $w_{\sigma}$ for some $w_{\sigma}$. Going to the limit for $\epsilon_{n} \rightarrow 0$ in (6.6) we obtain

$$
\begin{equation*}
\left\|D w_{\sigma}\right\|_{L^{\infty}\left(B_{\rho}, \mathbb{R}^{m \times n}\right)}^{2-\beta n} \leq C_{4}\left\{\int_{B_{R+\sigma}}(1+g(|D u|)) d x\right\}^{\frac{1}{1-\beta}+\epsilon} \tag{6.7}
\end{equation*}
$$

Hence we have that also $D w_{\sigma}$ is equibounded in $L^{\infty}\left(B_{\rho}, \mathbb{R}^{m \times n}\right)$ and it is still possible to take a subsequence which converges in the weak ${ }^{*}$ topology of $L^{\infty}\left(B_{\rho}, \mathbb{R}^{m}\right)$ to a function $D w$ for some $w$.
We will prove that $w=u$. Let us consider $\epsilon_{n}$ sufficiently small in dependence on $\sigma$; more precisely, fixed $\sigma$, we consider $\epsilon_{n} \leq \overline{\epsilon_{n}}(\sigma)$, with $\overline{\epsilon_{n}}(\sigma)$ such that $\frac{1}{\overline{\epsilon_{n}(\sigma)}}>\left[C_{5}(\sigma)\right]^{\frac{1}{2-\beta n}}$ where $C_{5}(\sigma)$ is the constant obtained in the estimate (6.6). Then we have by (6.6) that $\left|D u_{\epsilon_{n}, \sigma}\right|<\frac{1}{\epsilon_{n}}$. By the definition of $g_{\epsilon_{n}}(t)$ we can calculate

$$
g_{\epsilon_{n}}(t)= \begin{cases}\frac{g^{\prime}\left(\bar{t}+\epsilon_{n}\right)}{\bar{t}+t_{n}} \frac{t^{2}}{2} & \text { if } 0 \leq t \leq \bar{t}+\epsilon_{n}  \tag{6.8}\\ g(t)-g\left(\bar{t}+\epsilon_{n}\right)+\frac{g^{\prime}\left(\bar{t}+\epsilon_{n}\right)\left(\bar{t}+\epsilon_{n}\right)}{2} & \text { if } \bar{t}+\epsilon_{n}<t \leq \frac{1}{\epsilon_{n}}\end{cases}
$$

and hence we can write that

$$
\begin{equation*}
g(t) \leq g\left(\bar{t}+\epsilon_{n}\right)+g_{\epsilon_{n}}(t), \quad \bar{t}+\epsilon_{n} \leq t \leq \frac{1}{\epsilon_{n}} \tag{6.9}
\end{equation*}
$$

By lower semicontinuity and (6.9) we obtain

$$
\int_{B_{\rho}} g\left(\left|D w_{\sigma}\right|\right) d x \leq \liminf _{\epsilon_{n} \rightarrow 0} \int_{B_{R}} g\left(\left|D u_{\epsilon_{n}, \sigma}\right|\right) d x \leq \liminf _{\epsilon_{n} \rightarrow 0} \int_{B_{R}} g_{\epsilon_{n}}\left(\left|D u_{\epsilon_{n}, \sigma}\right|\right) d x
$$

From (6.4) and (5.10) we can deduce that $g_{\epsilon_{n}}\left(\left|D u_{\epsilon_{n}, \sigma}\right|\right)$ is bounded with respect to $\epsilon_{n}$ and then we can apply in (6.4) the dominate convergence theorem obtaining

$$
\liminf _{\epsilon_{n} \rightarrow 0} \int_{B_{R}} g_{\epsilon_{n}}\left(\left|D u_{\epsilon_{n}, \sigma}\right|\right) d x \leq \int_{B_{R}} g\left(\left|D u_{\sigma}\right|\right) d x \leq \int_{B_{R+\sigma}} g(|D u|) d x .
$$

By resuming we have, for every $\rho<R$,

$$
\begin{equation*}
\int_{B_{\rho}} g\left(\left|D w_{\sigma}\right|\right) d x \leq \int_{B_{R+\sigma}} g(|D u|) d x . \tag{6.10}
\end{equation*}
$$

Again by lower semicontinuity and by (6.10) we have

$$
\int_{B_{R}} g(|D w|) d x \leq \liminf _{\sigma \rightarrow 0} \int_{B_{R}} g\left(\left|D w_{\sigma}\right|\right) d x \leq \int_{B_{R}} g(|D u|) d x .
$$

Now, our assumptions on $g$ do not guaranty uniqueness of the minimizer for the Dirichlet problem. However $g(|\xi|)$ is locally strictly convex for $|\xi|>1$, then we can conclude as in [21] that $w=u$. Going to the limit for $\sigma \rightarrow 0$ in (6.7) we get

$$
\begin{equation*}
\|D w\|_{L^{\infty}\left(B \rho ; \mathbb{R}^{m \times n}\right)}^{2-\beta n} \leq C_{4}\left\{\int_{B_{R}}(1+g(|D u|)) d x\right\}^{\frac{1}{1-\beta}+\epsilon} \tag{6.11}
\end{equation*}
$$

Hence the estimate (6.11) holds also for $D u$. Therefore we completed the proof of Theorem A.

Theorem B follows by Theorem A with some simplifications; below we give an outline of its proof.

Outline of the proof of Theorem B. We first observe that the assumption (2.12) implies that $\lim _{t \rightarrow+\infty} g^{\prime}(t)=l \in(0,+\infty)$ and hence there exist $t_{0}$ such that $\frac{g^{\prime}(t)}{t}<1$ for every $t \geq t_{0}$. Thus, condition (2.13) can be rewrite as

$$
H\left(\frac{g^{\prime}(t)}{t}\right)^{\frac{2}{2^{*}}} t^{-2 \beta} \leq g^{\prime \prime}(t) \leq K \frac{g^{\prime}(t)}{t}, \quad \forall t \geq t_{0}
$$

where $\beta=\frac{\gamma}{2}-\frac{1}{2^{*}}$. Since the case $\gamma=1$, corresponding to the assumption $H \frac{1}{t} \leq$ $g^{\prime \prime}(t) \leq K \frac{1}{t}$, is easier to be treated, we limit ourselves to consider here $\gamma>1$; in this case we have $\beta=\frac{\gamma}{2}-\frac{1}{2^{*}}>\frac{1}{n}$ and we are in the conditions of Theorem A. Moreover, the function $g^{\prime}(t)$ has the $\Delta_{2}$ - property. This make immediate lemma 4.2 and that is why in the right hand side of final estimate (2.14) does not appear the exponent $\beta$ (see also Remark 1.2 and Remark 5.1 in [21]).

Acknowledgements. A referee pointed out to us that the first version of this paper presented for publication contained a mistake in the proof of Lemma 3.1. We corrected
the proof of Lemma 3.1 and its application in the proof of Lemma 4.2. The main Theorems A and B (stated at the end of section 2) remain unchanged with respect to the first version. We thank the referee for having read the paper in detail.

The research was partially supported by the Italian Ministero dell'Istruzione, dell'Università e della Ricerca (MIUR).
